Task

The following task was included in the Federal Fiscal Year 2024 Clean Water Act 604(b) Grant Workplan and Budget:

The Nevada Division of Environmental Protection (NDEP) will evaluate the climate vulnerability of Nevada's watersheds. This effort will rank the climate vulnerability of watersheds in Nevada based on a variety of metrics. Understanding which watersheds in Nevada are most vulnerable to stressors associated with climate change will help NDEP factor climate considerations into its water quality management program.

Executive Summary

According to the Fifth National Climate Assessment, the effects of human-caused climate change are already far-reaching and worsening across every region of the United States (Jay et al 2023). In recent decades, climate change has already impacted Nevada causing increased air temperatures, loss of snowpack, earlier snowmelt, increased evaporative demand, extreme droughts, and intensified wildfire activity (McAfee et al 2021). Climate change will continue to cause profound changes in the hydrologic cycle, increasing the risk of flooding, drought, and degraded water supplies for both people and ecosystems (Jay et al 2023). Even though climate change will impact every watershed in Nevada, it is important to understand the relative vulnerability of the 2,564 HUC₁₂s in the state to effectively allocate NDEP's time and resources.¹

Climate change is expected to have significant effects on surface water quality due to increases in river and lake temperatures, more frequent and severe precipitation events, decline in snowpack, changes in the magnitude and seasonality of runoff, increased evaporative demand, and more frequent and intense wildfires. Climate change indicators that will have the most influence on these effects include air temperature, precipitation, snowpack, runoff, evaporative deficit, and wildfire risk.

Indicator	How Climate Change Will Impact Indicator	Impact on Water Quality
Air Temperature		
Precipitation		Variable
Snowpack		
Annual Runoff		Variable
Evaporative Deficit		
Wildfire Risk		

Air Temperature

Climate change has already increased air temperatures across Nevada. Both the average annual daily high temperature and the average summer daily high temperature are projected to increase in all 2,564 HUC₁₂s in Nevada for the years 2061 to 2090 compared to the historical period of 1971 to 2000 (USEPA 2023a).

¹ HUC₁₂ is a 12-digit hydrologic unit code that delineates to a subwatershed level that captures tributary systems. HUC₁₂s typically represent subwatersheds that range from 10,000 to 40,000 acres.

Impact on Water Quality

There is a strong, direct relationship between increased air temperatures and elevated water temperatures in surface water bodies. These changes will also result in decreased dissolved oxygen concentrations in Nevada's surface water bodies. Based on the Projected Change in Annual Temperature in the HUC12 and Projected Change in Summer Temperature in the HUC12 indicators, water temperatures are expected to rise, and dissolved oxygen concentrations are expected to drop across Nevada which will degrade water quality.

Precipitation

Climate change has already altered precipitation patterns in Nevada. Annual precipitation has increased in the north and decreased south between 1901 and 2023. Both annual precipitation and summer precipitation are projected to increase in all 2,564 HUC12s in Nevada for the years 2061 to 2090 compared to the historical period of 1971 to 2000 (USEPA 2023a).

Impact on Water Quality

The relationship between precipitation and water quality is difficult to establish because precipitation influences water quality through many hydrological and biochemical mechanisms. The seasonality, frequency, and intensity of precipitation all influence whether changing precipitation patterns will improve or degrade water quality. Therefore, conclusions about the climate vulnerability of watersheds will not be drawn based on precipitation indicators because of the uncertainty of projections and the variability of how changes in precipitation will impact water quality in Nevada. However, it is important to understand how climate change will impact precipitation patterns in Nevada, so projections of future changes in precipitation relative to historical conditions are included in this report.

Snowpack

Climate change has already caused a decline in mountain snowpack and snowmelt to occur earlier in the year than in the past in Nevada. 242 HUC12s in Nevada have a projected decrease in March snow water equivalence (SWE) of 100% meaning that spring snowpack will no longer be present in these subwatersheds in the future.² 2,056 HUC12 in Nevada have a projected decrease in March SWE between 25.38% and 99.64%. The remaining 266 HUC12s in Nevada have a projected decrease in March SWE of 0% but were removed from this vulnerability assessment because they likely never had snowpack in March regardless of climate change (USEPA 2023a).³

² SWE is a measurement of the amount of liquid water contained within the snowpack.

³ Most of the 226 HUC12s with a projected decrease in March SWE of 0% are in low elevation areas of southern Nevada where snowfall is infrequent.

Impact on Water Quality

A reduced snowpack that melts earlier in the year will result in degraded surface water quality in Nevada.

Runoff

Average annual surface runoff is projected to decrease in 42 percent of HUC12s in Nevada and increase in 58 percent of HUC12s in Nevada for the years 2061 to 2090 relative to historical conditions from 1971 to 2000 (USEPA 2023a).

Impact on Water Quality

The relationship between runoff and water quality is difficult to establish because runoff influences water quality through many hydrological and biochemical mechanisms. The seasonality, frequency, and intensity of runoff all influence whether changing runoff patterns will improve or degrade water quality. Therefore, conclusions about the climate vulnerability of watersheds will not be drawn based on runoff indicators because of the variability of how changes in runoff will impact water quality in Nevada. However, it is important to understand how climate change will impact runoff patterns in Nevada so projections of future changes in runoff relative to historical conditions are included in this report.

Evaporative Deficit

Over the past 40 years, evaporative demand has strongly increased in Nevada, with the fastest increases in the west-central part of the state. Climate projections indicate that evaporative demand will continue to increase in Nevada (NV 2021). Evaporative deficit is a measure of aridity or atmospheric water shortage, quantified as the difference between potential evapotranspiration and actual evapotranspiration. Annual evaporative deficit is projected to increase (i.e., drier conditions) in all 2,564 HUC12s in Nevada from 2061 to 2090 relative to historical conditions from 1971 to 2000 (USEPA 2023a).

Impact on Water Quality

There is a strong, direct relationship between increased evaporative deficit and degraded surface water quality. Therefore, water quality across Nevada will be degraded because of increased annual evaporative deficit.

Wildfire

Wildfire frequency, severity, and areal extent have already increased in Nevada. Climate change will continue to increase the frequency, severity, and areal extent of wildfires across Nevada (McAfee et al 2021).

Impact on Water Quality

There is a strong, direct relationship between wildfire occurrence and degraded surface water quality. Surface water quality will be degraded in HUC12s where wildfires occur.

Methodology

Recovery Potential Screening (RPS) is a systematic, comparative method for identifying differences among watersheds (or watershed-based, hydrologic units such as HUC₁₂s). RPS provides water programs with an easy to use, desktop screening and comparison tool that is user-customizable for the geographic area of interest and a variety of specific comparison and prioritization purposes. The RPS website offers a flexible framework of methods, technical information, and tools that can be tailored to any watershed program or purpose.⁴ As a result, BWQP chose to use RPS as the foundation for the climate vulnerability evaluation of Nevada's watersheds. BWQP used data from the Excel RPS Tool – Standard File released in November 2023 to inform this project (USEPA 2023a).

To begin, BWQP selected the climate change-related stressor indicators expected to have the largest impact on surface water quality in Nevada.

- Projected Change in Annual Temperature in the HUC₁₂
- Projected Change in Summer Temperature in the HUC₁₂
- Projected Change in Annual Precipitation in the HUC₁₂
- Projected Change in Summer Precipitation in the HUC₁₂
- Projected Percent Decrease in March Snow Water Equivalence in the HUC₁₂
- Projected Percent Change in Annual Surface Runoff in the HUC₁₂
- Projected Percent Change in Annual Evaporative Deficit in the HUC₁₂
- PHWA Wildfire Vulnerability Sub-Index, State

For each of these stressor indicators, the RPS Tool includes a value for all 2,564 HUC₁₂s in Nevada. Thus, BWQP was able to rank the vulnerability of the HUC₁₂s in Nevada from most vulnerable (least resilient) to least vulnerable (most resilient) for each indicator.⁵ For example, HUC₁₂ 160203061602 has the largest projected change in annual temperature in Nevada of 3.81 degrees Celsius (°C). Therefore, HUC₁₂ 160203061602 is ranked as the most vulnerable (least resilient) HUC₁₂ to projected changes in annual temperature (Rank 1). On the other hand, HUC₁₂ 150301020303 has the smallest projected change in annual temperature in Nevada of 3.31°C. Therefore, HUC₁₂ 150301020303 is the least vulnerable (most resilient) HUC₁₂ to projected changes in annual temperature (Rank 2,564). It is important to note that even though HUC₁₂ 150301020303 has the smallest projected change

⁴ Recovery Potential Screening (RPS) - Comparing Watershed Condition and Restorability (<https://www.epa.gov/rps>).

⁵ The relationships between precipitation and runoff with water quality are difficult to establish because precipitation and runoff influence water quality through many hydrological and biochemical mechanisms. The seasonality, frequency, and intensity of precipitation and runoff all influence whether changing precipitation and runoff patterns will improve or degrade water quality. Therefore, conclusions about the climate vulnerability of watersheds will not be drawn based on precipitation and runoff indicators because of the uncertainty of how changes in precipitation and runoff will impact water quality in Nevada. However, it is important to understand how climate change will impact precipitation and runoff patterns in Nevada, so projections of future changes in precipitation and runoff relative to historical conditions are included in this report.

in annual temperature in Nevada, the impacts of a 3.31°C increase in annual temperature will be significant.

BWQP created the vulnerability summary tables and figures in this report using the Quantile breaks data classification method⁶ to divide indicator values into five categories of vulnerability:

Climate Vulnerability Range
Most Vulnerable (Least Resilient)
More Vulnerable
Medium Vulnerable
Less Vulnerable
Least Vulnerable (Most Resilient)

Purpose

Climate change will impact the chemical, physical, and biological integrity of surface waters in every watershed in Nevada, however some watersheds are more vulnerable to these impacts than others.⁷ Understanding which watersheds in Nevada are most vulnerable to stressors associated with climate change will help NDEP factor climate considerations into its water quality management programs to restore and maintain the chemical, physical, and biological integrity of Nevada’s surface waters.

Introduction

Clean fresh water is essential to life on the Earth, and climate change has already affected and will continue to impact the planet’s water resources. As the climate warms, changing precipitation patterns, decreasing amounts of snow, earlier snowmelt, and drought all pose risks to water quality and supplies in Nevada, affecting communities, livelihoods, and ecosystems (USEPA 2024a).

A changing climate will have direct and cascading effects on water quality in Nevada. Assessing potential risks, however, is complicated as water quality is influenced by multiple interacting climatic, watershed (e.g., physiographic setting, land use), and human factors with high spatial and temporal variability (Johnson et al 2022).

⁶ The Quantile breaks data classification method distributes observations equally across the class interval, giving unequal class widths but the same frequency of observations per class (ESRI 2024).

⁷ Even though a watershed is less vulnerable to climate change, the impacts to water quality may still be significant.

The effects of climate change on water quality will vary in different regional and watershed settings, and are strongly mediated by physical setting (e.g., geology, topography), land use, and the human use and management of water. Effects on water quality are also better understood for some attributes than others; for example, water temperatures are very likely to increase in Nevada, whereas changes in nonpoint loading of nutrients, sediment, and other pollutants from upland sources to water bodies will vary across locations and are closely linked to changes in precipitation and runoff (Johnson et al 2022).

According to the Fifth National Climate Assessment, the effects of human-caused climate change are already far-reaching and worsening across every region of the United States (Jay et al 2023). In recent decades, climate change has already impacted Nevada causing increased air temperatures, loss of snowpack, increased evaporative demand, extreme droughts, and intensified wildfire activity (McAfee et al 2021). Climate change will continue to profoundly alter the hydrologic cycle, increasing the risk of flooding, drought, and degraded water supplies for both people and ecosystems (Jay et al 2023). Even though climate change will impact every watershed in Nevada, it is important to understand the relative vulnerability of the 2,564 HUC₁₂s in the state to effectively allocate NDEP's time and resources.

Air Temperature and Water Quality

Air temperature is an important climate variable in the water balance and other ecosystem processes. Air temperature changes profoundly affect the hydrologic cycle. Increased air temperatures may increase the relative distribution of rain versus snowfall in a watershed, increase water loss into the atmosphere through evapotranspiration, and accelerate snowmelt. Changes in precipitation patterns can magnify these hydrologic effects and alter the amount and the quality of water available for aquatic life, drinking water, and recreation (USEPA 2022a).

Warmer air can also elevate water temperatures in rivers, lakes, and other surface water bodies through air-to-water heat transfer and when runoff encounters warmed surfaces. Increased air temperatures can affect water quality, water quantity, and aquatic ecosystem health in a variety of ways (USEPA 2022a).

Water temperature exerts a major influence on biological activity and growth and governs the kinds of organisms that live in water bodies. Fish, insects, zooplankton, phytoplankton, and other aquatic species all have temperature ranges outside of which they will not survive (USGS 2018).

Water temperature is also important because of its influence on water chemistry. In general, increased water temperature can result in:

- Decreased dissolved oxygen which impacts the survival, growth, and reproduction of aquatic life.
- Higher conductivity.⁸
- Increased rate of chemical reactions.
- Increased solubility of metals and other toxic materials in water.
- Increased toxicity of some substances to aquatic life.
- Increased survival rates of waterborne pathogens.
- Increased likelihood of harmful algal blooms, which typically occur during the summer season or periods of unusually warm temperatures. Algal blooms negatively impact aquatic life and water quality (USEPA 2021a and 2022a).⁹

⁸ Warmer water also dissolves more minerals from the surrounding rock and will therefore have a higher conductivity (USGS 2018).

⁹ Algal community species composition in a waterbody often changes with temperature. For example, diatoms most often are the dominant algal species at water temperatures of 20° to 25°C, green algae at 30° to 35°C, and cyanobacteria (blue-green algae) above 35°C (USEPA 1999).

Table 1: Potential effects of short- and long-term increases in temperature on aquatic life

Short-Term Summer Heat Stress	Long-Term Temperatures Increases
• Reduced or blocked sexual maturation. • Inhibited or blocked critical stages of larval development. • Reduced feeding and reduced growth of juveniles and adults. • Increased susceptibility to predation. • Reduced productivity of macroalgae and seagrasses. • Increased death, organisms forced to leave, and increased incidence of disease or parasitism.	• Loss of aquatic species whose survival and breeding are temperature dependent. • Change in the abundance and spatial distribution of aquatic species and reduced populations of some species. • Increase in rates of evaporation from surface water, causing increased salinity and waterbody shrinkage, resulting in a loss of habitat.

Water temperature has been increasing in many rivers and lakes, and the length of time that lakes and reservoirs are thermally stratified has also increased. Reduced mixing, elevated water temperatures, and biotic consumption of dissolved oxygen may lead to deteriorated water quality in lakes and ponds across the United States (Boehlert et al. 2015).

Water temperature is already a significant concern in Nevada causing the second greatest number of impairments in Nevada (89 = 12.8% of all impairments (NDEP 2024)). As climate change leads to even further increases in water temperature, these impairments will likely become even more pervasive.

How Climate Change Will Impact Air Temperature in Nevada

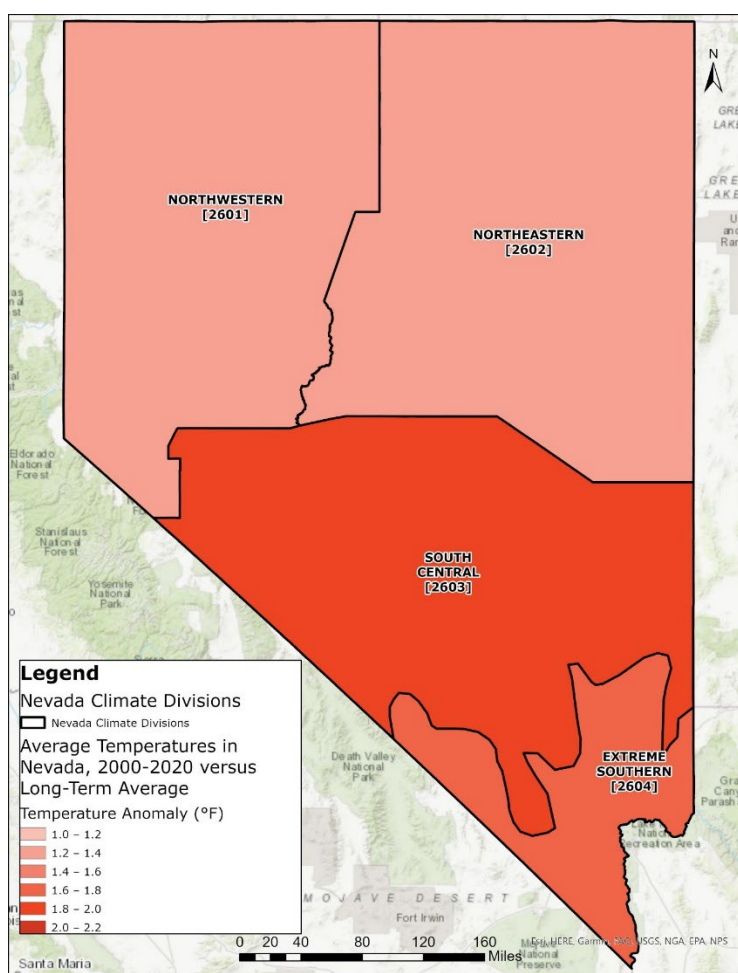

Climate change has already increased air temperatures across Nevada. USEPA (2024a) indicates that average air temperatures from 2000 to 2020 were over 1 degree Fahrenheit °F higher than the long-term average (1895 to 2020). **Table 1** and **Figure 1** present the percent change in average air temperatures compared with the long-term average (USEPA 2024a and e).

Table 2: Average Temperatures in Nevada, 2000-2020 versus Long-Term Average

Nevada Climate Division	Temperature Anomaly
1 – Northwestern (2601)	1.33°F (0.74°C)
2 – Northeastern (2602)	1.33°F (0.74°C)
3 – South Central (2603)	1.93°F (1.07°C)
4 – Extreme Southern (2604)	1.77°F (0.98°C)

(USEPA 2024a)

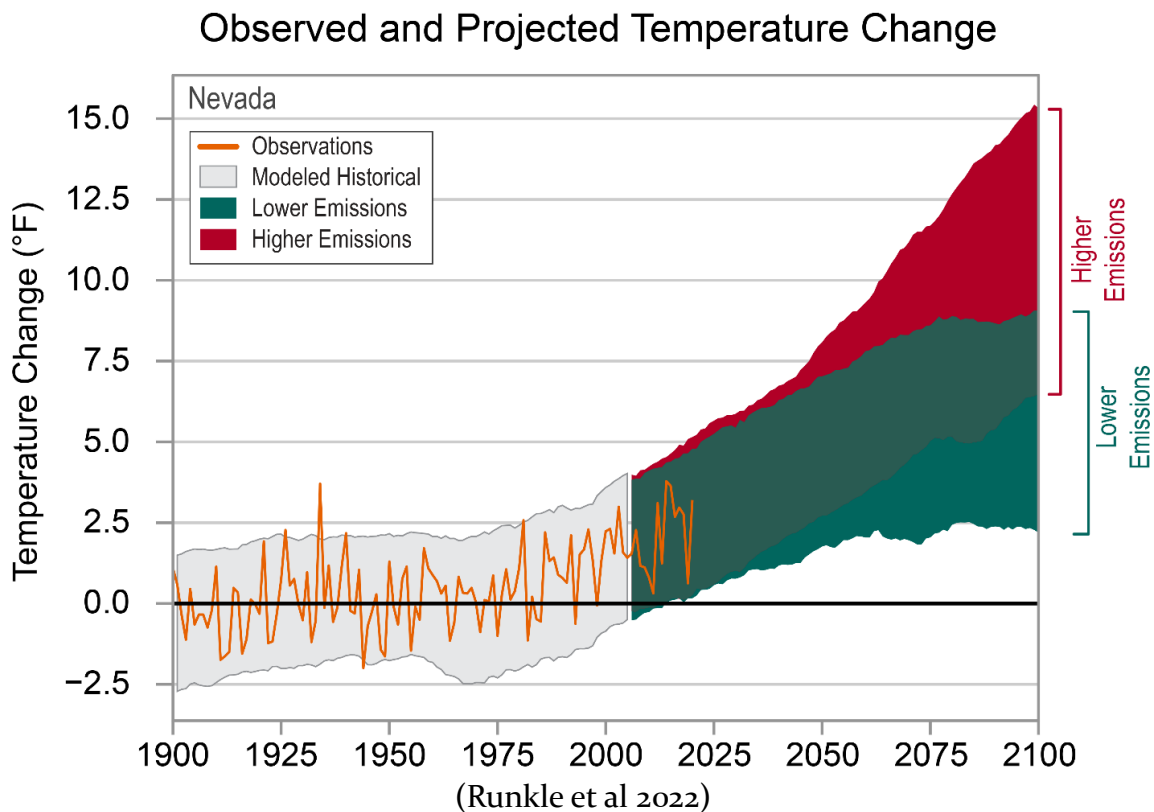

Figure 1: Average Temperatures in Nevada, 2000-2020 versus Long-Term Average

(USEPA 2024a)

According to the National Oceanic and Atmospheric Administration, historically unprecedented warming is projected to continue in Nevada throughout this century under a higher emissions pathway, with associated increases in heat wave intensity and decreases in cold wave intensity. Even under a lower emissions pathway, annual average temperatures are projected to exceed historical record levels by the middle of this century. However, a large range of temperature increases is projected under both pathways, and under the lower pathway, a few projections are only slightly warmer than historical records (Runkle et al 2022).

Figure 2: Observed and Projected Temperature Change in Nevada

With high confidence, climate models predict that average air temperatures will continue to rise throughout Nevada. The amount of warming that Nevada will face in the future depends on whether greenhouse gas emissions continue to grow or whether they are reduced rapidly over the coming decades. Nevada would experience greater warming with higher emissions. Projections of warming range from 4°F to 6°F (2.22°C to 3.33°C) throughout Nevada in the near term (the next few decades), but long-term (the last few decades of the 21st century) changes depend on society's emissions-related choices today (McAfee et al 2021).

Indicator: Projected Change in Annual Temperature in HUC12

The **Projected Change in Annual Temperature in the HUC12** indicator measures projected future changes in average annual air temperature relative to historical conditions in a HUC12. This indicator depicts the difference in average annual daily high temperature in the HUC12 that is projected for the years 2061 to 2090 compared to the historical period of 1971 to 2000, reported in °C. Positive values indicate a projected increase in average annual temperature during 2061-2090 relative to historical 1971-2000 conditions (negative values indicate a projected decrease). This indicator reflects the projection for a high greenhouse gas emission scenario, known as Representative Concentration Pathway (RCP) 8.5. Under this scenario, an increase in greenhouse gas emissions continues through the year 2100 (USEPA 2022a and 2024b).¹⁰

This indicator can be used to build awareness of projected temperature changes in one or more HUC12s and to assess the vulnerability of HUC12s to future degradation due to climate change (USEPA 2022a).

The average annual daily high temperature is projected to increase in all 2,564 HUC12s in Nevada (USEPA 2023a).

Table 3: Projected Change in Annual Temperature Vulnerability Summary

Climate Vulnerability Range	Projected Change in Annual Temperature (°C)	HUC12 Ranking
Most Vulnerable (Least Resilient)	3.750001 – 3.810000	1 - 398
More Vulnerable	3.710001 – 3.750000	399 - 870
Medium Vulnerable	3.660001 – 3.710000	871 - 1,479
Less Vulnerable	3.550001 – 3.660000	1,480 - 2,021
Least Vulnerable (Most Resilient)	3.310000 – 3.550000	2,022 - 2,564

(USEPA 2023a)

See **Appendix A: Projected Change in Annual Temperature Data** for the full data set.

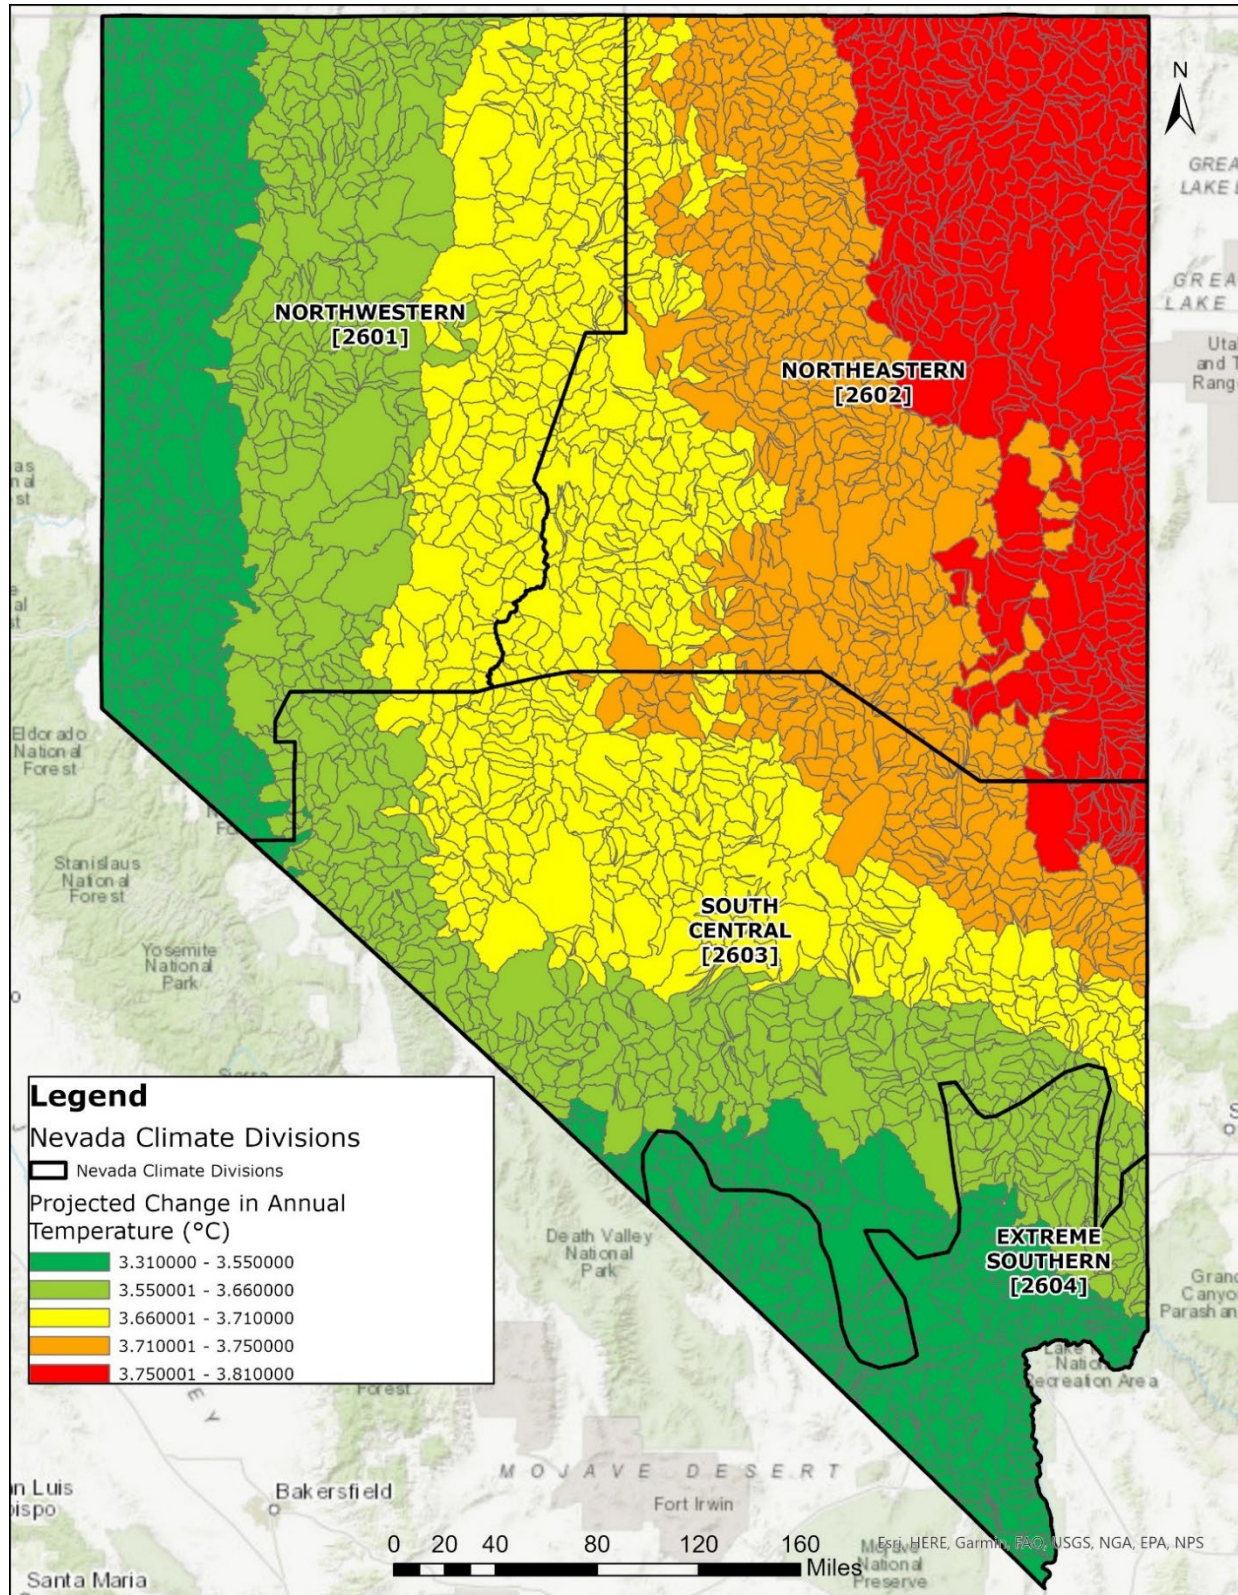

Indicator Takeaway

There is a strong, direct relationship between increased air temperatures and elevated water temperatures in surface water bodies. These changes will also result in decreased dissolved oxygen concentrations in Nevada's surface water bodies. Based on this indicator,

¹⁰ Average annual temperature during the future and historical periods is calculated from results of 30 climate models summarized by the USGS National Climate Change Viewer program (<https://www2.usgs.gov/landresources/lcs/nccv.asp>) (USEPA 2024b).

water temperatures are expected to rise, and dissolved oxygen concentrations are expected to drop across Nevada which will degrade water quality.

Figure 3: Projected Change in Annual Temperature (°C)

Indicator: Projected Change in Summer Temperature in HUC12

The **Projected Change in Summer Temperature in the HUC12** indicator measures projected future changes in average summer air temperature relative to historical conditions in a HUC12 subwatershed. This indicator depicts difference in the average summer daily high temperature in the HUC12 that is projected for the years 2061 to 2090 compared to the historical period of 1971 to 2000, reported in degrees Celsius. Summer is defined as May 1st through October 31st. Positive values indicate a projected increase in average summer temperature during 2061-2090 relative to historical 1971-2000 conditions; negative values indicate a projected decrease. This indicator reflects the projection for the RCP 8.5 greenhouse gas emission scenario (USEPA 2022a and 2024b).¹¹

This indicator can be used to build awareness of projected temperature changes in one or more HUC12s and to assess the vulnerability of HUC12s to future degradation due to climate change (USEPA 2022a).

The average summer daily high temperature is projected to increase in all 2,564 HUC12s in Nevada (USEPA 2023a).

Table 4: Projected Change in Summer Temperature Vulnerability Summary

Climate Vulnerability Range	Projected Change in Summer Temperature (°C)	HUC12 Ranking
Most Vulnerable (Least Resilient)	3.880001 – 3.970000	1 – 457
More Vulnerable	3.840001 – 3.880000	458 – 936
Medium Vulnerable	3.780001 – 3.840000	937 – 1,492
Less Vulnerable	3.680001 – 3.780000	1,493 – 2,013
Least Vulnerable (Most Resilient)	3.370000 – 3.680000	2,014 – 2,564

(USEPA 2023a)

See **Appendix B: Projected Change in Summer Temperature Data** for the full data set.

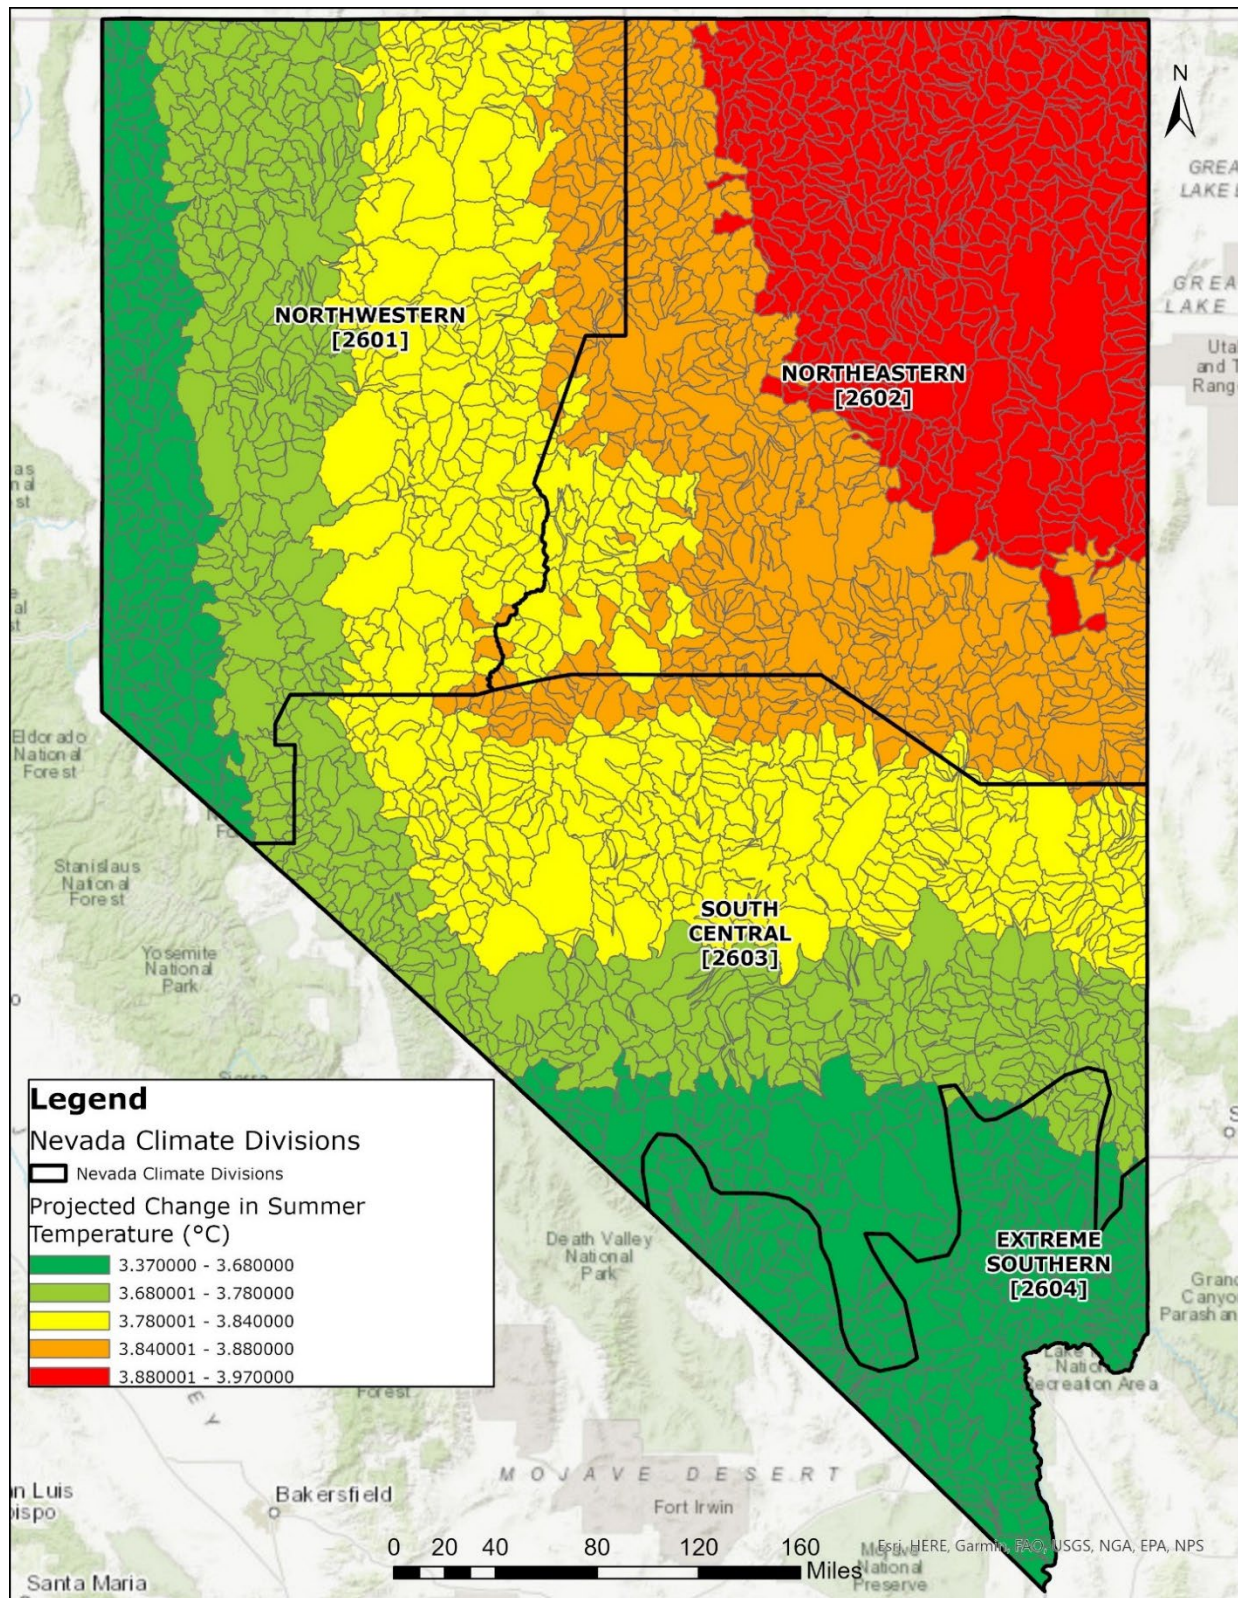

Indicator Takeaway

There is a strong, direct relationship between increased summer air temperatures and elevated water temperatures in surface water bodies. These changes will also result in decreased dissolved oxygen concentrations in Nevada's surface water bodies. Summer is a critical time of year for several beneficial uses including aquatic life, irrigation, propagation of wildlife, recreation, and watering of livestock. Based on this indicator,

¹¹ Average summer temperature during the future and historical periods is calculated from results of 30 climate models summarized by the USGS National Climate Change Viewer program (<https://www2.usgs.gov/landresources/lcs/nccv.asp>) (USEPA 2024b).

summer water temperatures are expected to rise, and dissolved oxygen concentrations are expected to drop across Nevada which will degrade water quality.

Figure 4: Projected Change in Summer Temperature (°C)

(USEPA 2023a)

Precipitation and Water Quality

Precipitation is a fundamental component of the water cycle and occurs when water falls from the atmosphere as rain or snow. Nevada is the driest state in the nation, the statewide annual average (1895–2020) precipitation is only 10.2 inches. Regionally, annual average (1991–2020) precipitation varies from 4 inches in some low elevation locations in the southwest to more than 50 inches on high mountain peaks of the Sierra Nevada (Runkle et al 2022).

Rainfall, snowfall, and the timing of snowmelt affect the quantity and quality of water in surface water bodies. The seasonality, frequency, and intensity of precipitation all influence whether changing precipitation patterns will improve or degrade water quality.

Increased precipitation can improve water quality by increasing base streamflow. Increased base streamflow, especially during the summer, is important to dilute pollutants, decrease stream temperatures and increase dissolved oxygen in the water column. Many rivers and streams that violate water quality standards for common pollutants do so when flows are low. The amount of water in a stream or river also affects its resistance to becoming too warm, because more water takes longer to heat. Higher flows can protect sensitive, cold-water species like trout from harmful or even lethal water temperatures (USEPA 2024d).

Generally, increases in the frequency and severity of precipitation result in additional and more intense surface runoff which degrades water quality. Concentrations of many nonpoint source pollutants have a direct relationship with streamflow. Increased precipitation can intensify erosion and flush additional pollutants from land into water bodies. Such increases in sediment and pollutant delivery can degrade water supplies, inhibit recreational uses, and harm aquatic life. Extreme floods can further increase pollutant levels due to inadequate or failing drainage, flood control, or wastewater infrastructure (USEPA 2022c).

To further complicate matters, areas with increased precipitation will not necessarily have more water available for people and ecosystems, because higher temperatures also lead to increased evaporative demand (USEPA 2016 and 2024a). Areas that are projected to have higher air temperatures and smaller increases in annual and summer precipitation are likely more vulnerable to climate change because they may be subject to prolonged periods of drought. During drought conditions, low water levels can stress aquatic life and reduce the ability of waterbodies to dilute wastewater discharges. Less rain and snowfall can also cause lower water levels in wetlands, riparian zones, and floodplains that are vital habitats for aquatic species and disconnect these areas from nearby waterbodies (USEPA 2022c).

The relationship between precipitation and water quality is difficult to establish because precipitation influences water quality through many hydrological and biochemical mechanisms.

How Climate Change Will Impact Precipitation in Nevada

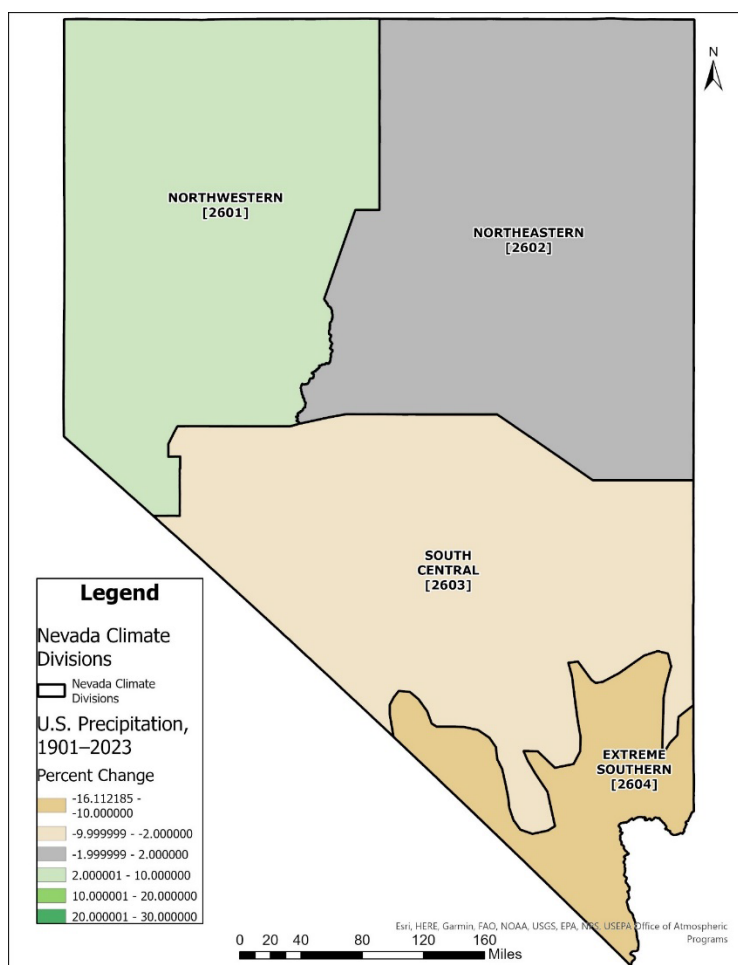

Precipitation patterns have already changed in Nevada. Annual precipitation has increased in the north and decreased south between 1901 and 2023. **Table 5** and **Figure 5** present the percent change in total annual precipitation compared with the average precipitation from 1901 to 2000 (USEPA 2024a and e).

Table 5: Percent Change in Total Annual Precipitation in Nevada, 1901-2023

Nevada Climate Division	Change in Total Annual Precipitation, 1901-2023
1 – Northwestern (2601)	4.76%
2 – Northeastern (2602)	1.16%
3 – South Central (2603)	-2.29%
4 – Extreme Southern (2604)	-11.71%

(USEPA 2024a and e)

Figure 5: Percent Change in Total Annual Precipitation in Nevada, 1901-2023

(USEPA 2024a and e)

Climate change can affect the intensity and frequency of precipitation. Warmer oceans increase the amount of water that evaporates into the air. When more moisture-laden air moves over land or converges into a storm system, it can produce more intense precipitation. As warmer temperatures cause more water to evaporate from the land and oceans, changes in the size and frequency of heavy storms could in turn affect the size and frequency of river flooding (USEPA 2024a).

Future projections of annual precipitation in Nevada are uncertain (Runkle et al 2022). It's not clear how precipitation might change. Based on different greenhouse gas scenarios, some models project more, some less, and some essentially no change (McAfee et al 2021).

It is important to understand how climate change will impact precipitation patterns in Nevada so projections of future changes in precipitation relative to historical conditions are included in this report. However, conclusions about the climate vulnerability of watersheds will not be drawn based on precipitation indicators because of the uncertainty of how changes in precipitation will impact water quality in Nevada.

Indicator: Projected Percent Change in Annual Precipitation

The **Projected Percent Change in Annual Precipitation in the HUC12** indicator measures projected future changes in average annual precipitation relative to historical conditions in a HUC12 subwatershed. This indicator depicts average annual precipitation in the HUC12 that is projected for the years 2061 to 2090, expressed as a percentage change from the historical annual average during 1971 to 2000. Positive values indicate a projected increase in average annual precipitation during 2061-2090 relative to historical 1971-2000 conditions; negative values indicate a projected decrease. This indicator reflects the RCP 8.5 greenhouse gas emission scenario (USEPA 2022c and 2024b).¹²

This indicator can be used to build awareness of how rain and snowfall totals are projected to change in one or more HUC12s (USEPA 2022c).

Annual precipitation is projected to increase in all 2,564 HUC12s in Nevada (USEPA 2023a).

Table 6: Projected Change in Annual Precipitation Summary

Change Category	Projected Change in Annual Precipitation	HUC12 Ranking
Smallest Increase	4.810000% – 9.240000%	1 – 859
Medium Increase	9.240001% – 9.900000%	860 – 1,718
Largest Increase	9.900001% – 15.020000%	1,719 – 2,564

(USEPA 2023a)

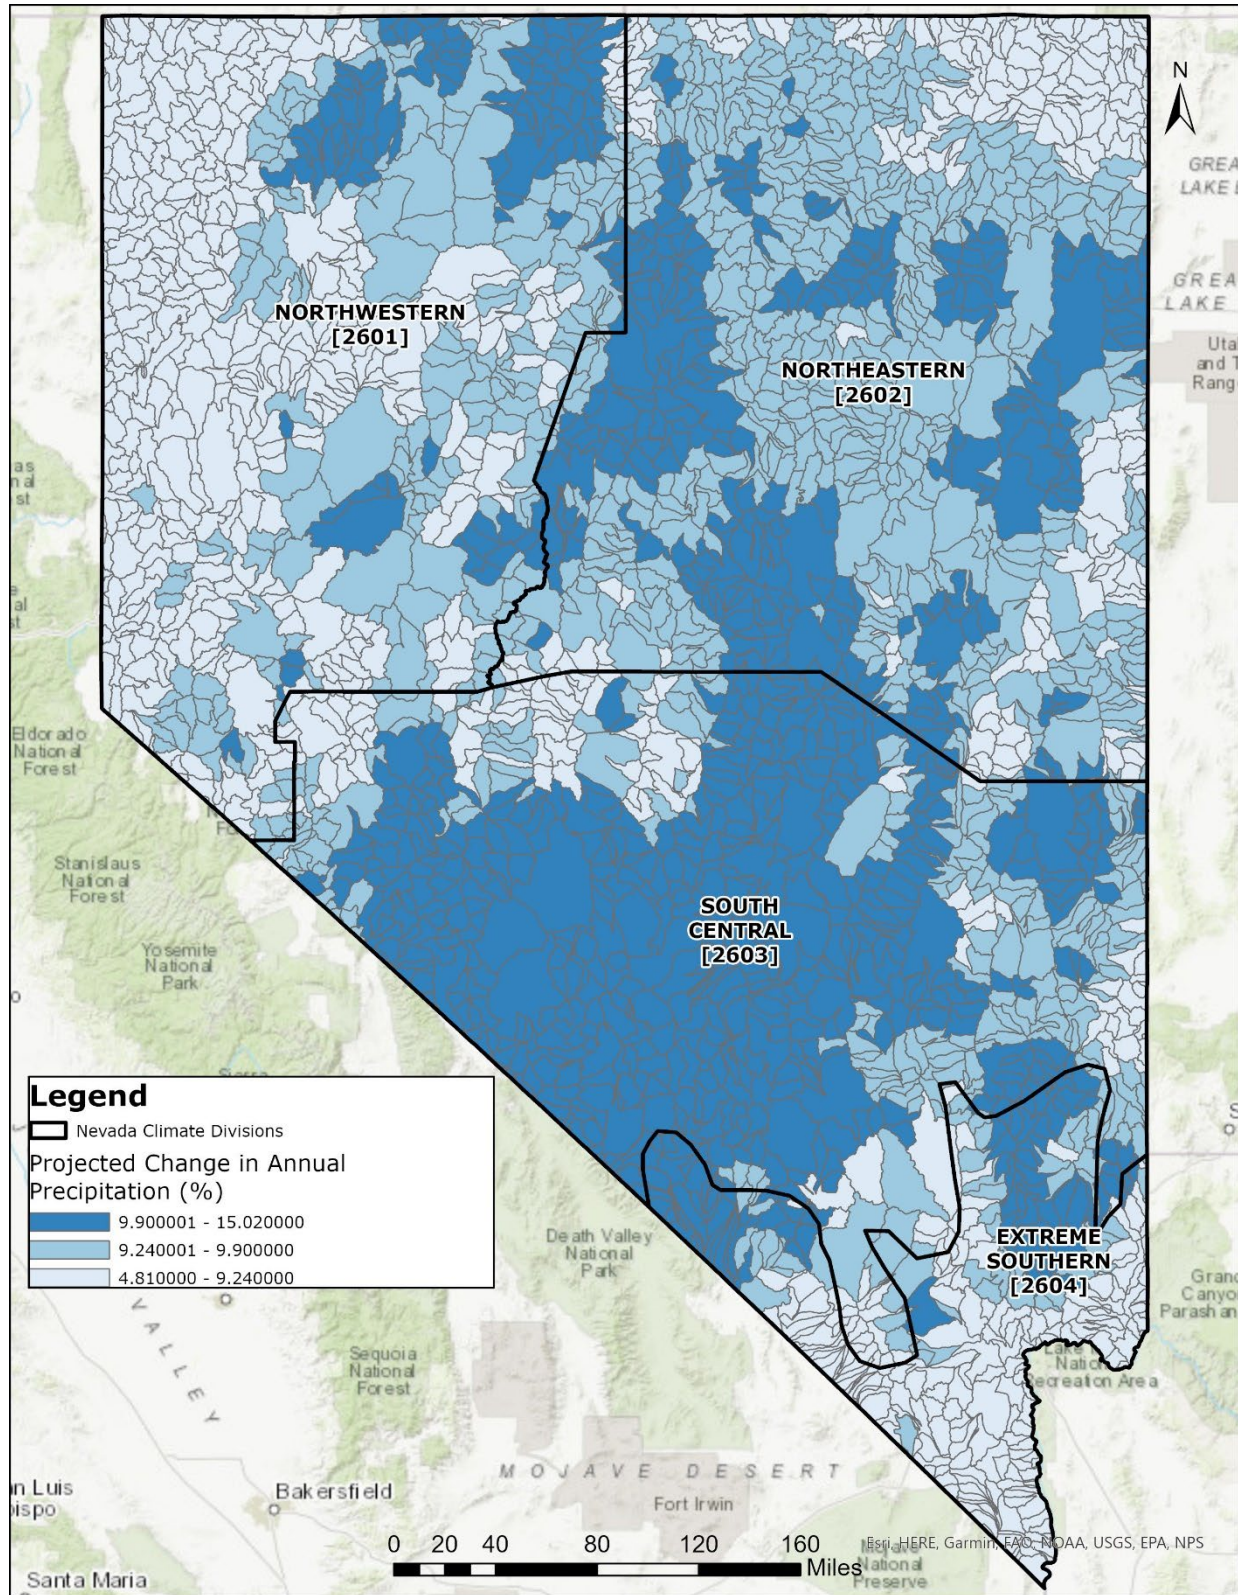

See **Appendix C: Projected Percent Change in Annual Precipitation Data** for the full data set.

Indicator Takeaway

Conclusions about the climate vulnerability of watersheds will not be drawn based on precipitation indicators because of the uncertainty of projections and the variability of how changes in precipitation will impact water quality in Nevada.

¹² Average precipitation during the future and historical periods is calculated from results of 30 climate models summarized by the USGS National Climate Change Viewer program (<https://www2.usgs.gov/landresources/lcs/nccv.asp>) (USEPA 2024b).

Figure 6: Projected Change in Annual Precipitation (%)

Indicator: Projected Percent Change in Summer Precipitation

The **Projected Percent Change in Summer Precipitation in the HUC12** indicator measures projected future changes in average summer precipitation relative to historical conditions in a HUC12 subwatershed. This indicator represents average summer precipitation in the HUC12 that is projected for the years 2061 to 2090, expressed as a percentage change from the historical summer average during 1971 to 2000. Summer is defined as May 1st to October 31st. Positive values indicate a projected increase in summer annual precipitation during 2061-2090 relative to historical 1971-2000 conditions; negative values indicate a projected decrease. This indicator reflects the RCP 8.5 greenhouse gas emission scenario (USEPA 2022c and 2024b).¹³

This indicator can be used to build awareness of how rain and snowfall totals are projected to change in one or more HUC12s and to assess the vulnerability of HUC12s to future degradation due to climate change.

Summer precipitation is projected to increase in all 2,564 HUC12s in Nevada (USEPA 2023a).

Table 7: Projected Change in Summer Precipitation Summary

Change Category	Projected Change in Summer Precipitation	HUC12 Ranking
Smallest Increase	2.290000% – 7.540000%	1 – 855
Medium Increase	7.240001% – 8.420000%	856 – 1,711
Largest Increase	8.420001% – 15.590000%	1,712 – 2,564

(USEPA 2023a)

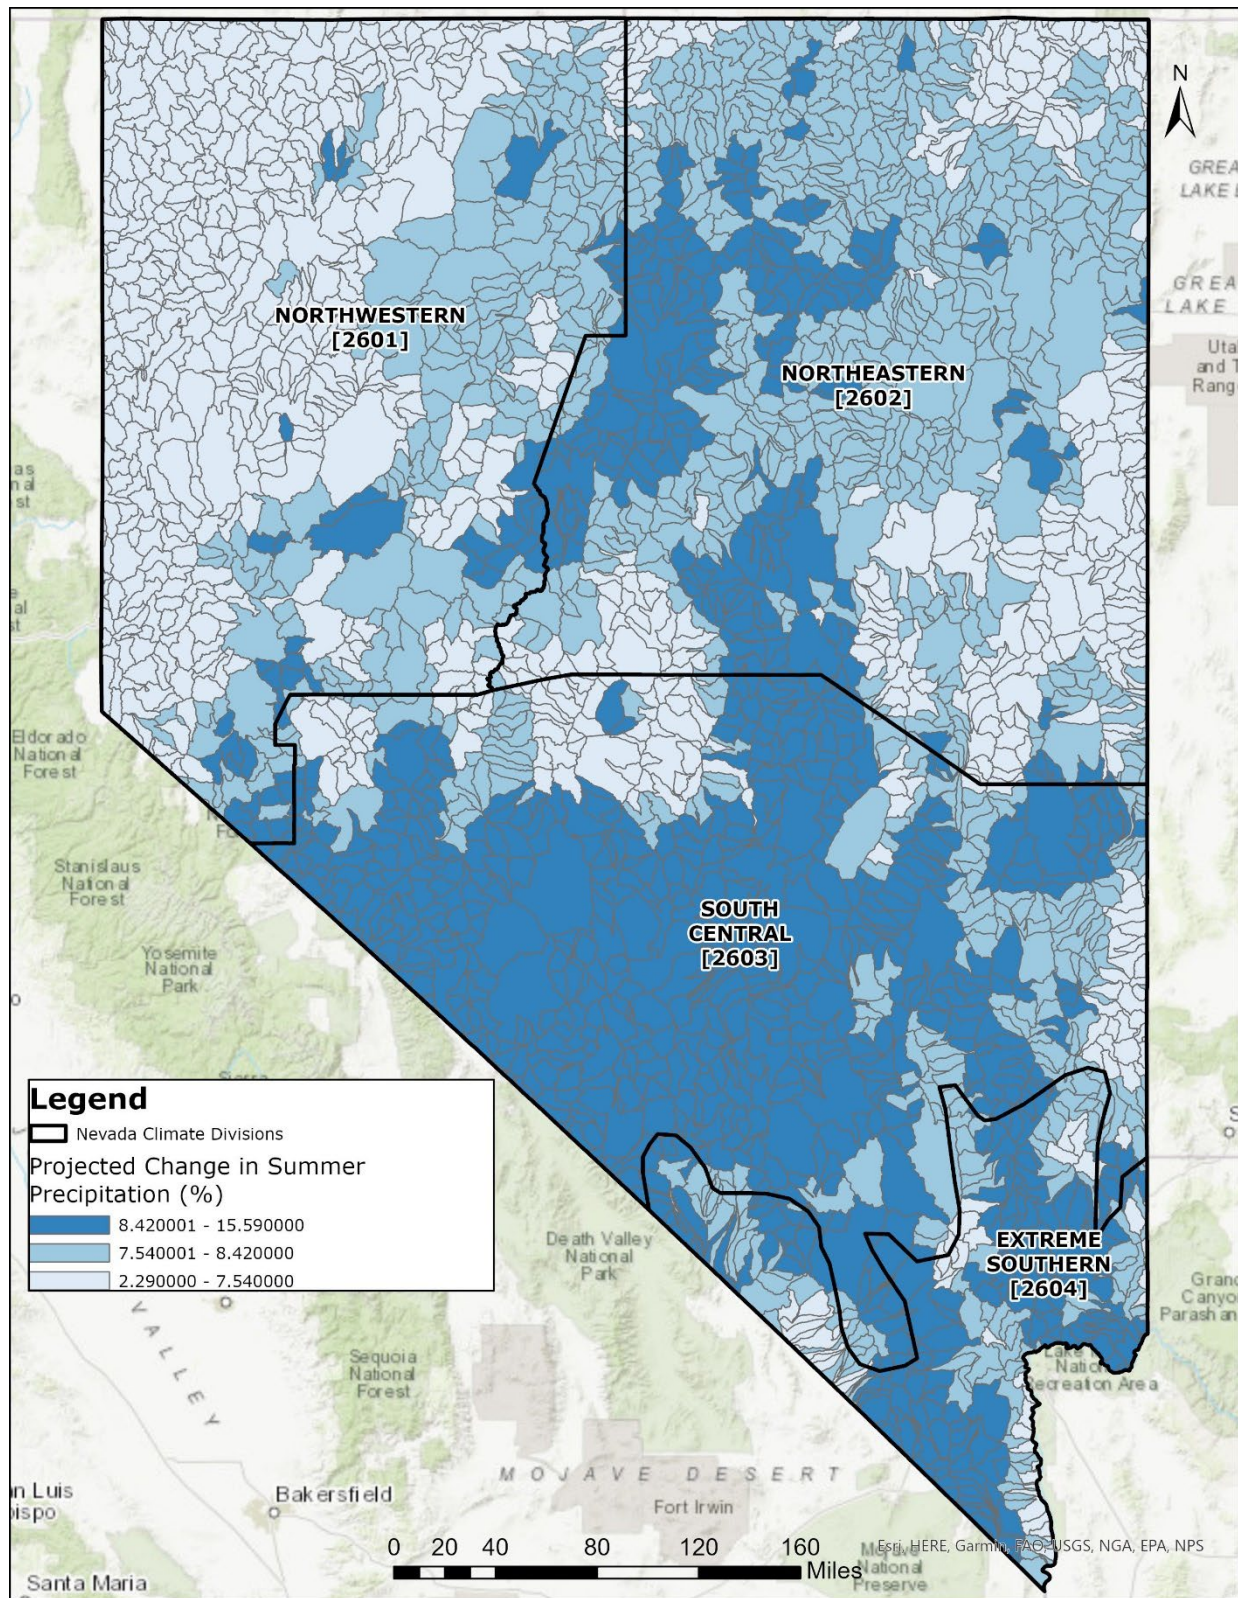

See **Appendix D: Projected Percent Change in Summer Precipitation Data** for the full data set.

Indicator Takeaway

Conclusions about the climate vulnerability of watersheds will not be drawn based on precipitation indicators because of the uncertainty of projections and the variability of how changes in precipitation will impact water quality in Nevada.

¹³ Summer precipitation during the future and historical periods is calculated from results of 30 climate models summarized by the USGS National Climate Change Viewer program (<https://www2.usgs.gov/landresources/lcs/nccv.asp>) (USEPA 2024b).

Figure 7: Projected Change in Summer Precipitation (%)

(USEPA 2023a)

Snowpack and Water Quality

People and wildlife depend on spring snowmelt to replenish water supplies; thus, decreased snow water equivalence (SWE) can contribute to water shortages.¹⁴ Snowpack changes are also associated with altered timing of peak flows in rivers, which can disrupt aquatic life processes, such as fish spawning and reproduction (USEPA 2022b). Throughout Nevada, snow-dominated watersheds provide most of the water supply for both human and environmental demands (McEvoy et al 2012). Mountain snowpack in Nevada is already in decline. Snowpack has decreased at 25 of 76 monitoring sites (70 percent) in Nevada since the 1950s (USEPA 2024f). **Table 8** and **Figure 8** present the trends in April snowpack in Nevada from 1955 to 2023 (USEPA 2024f).

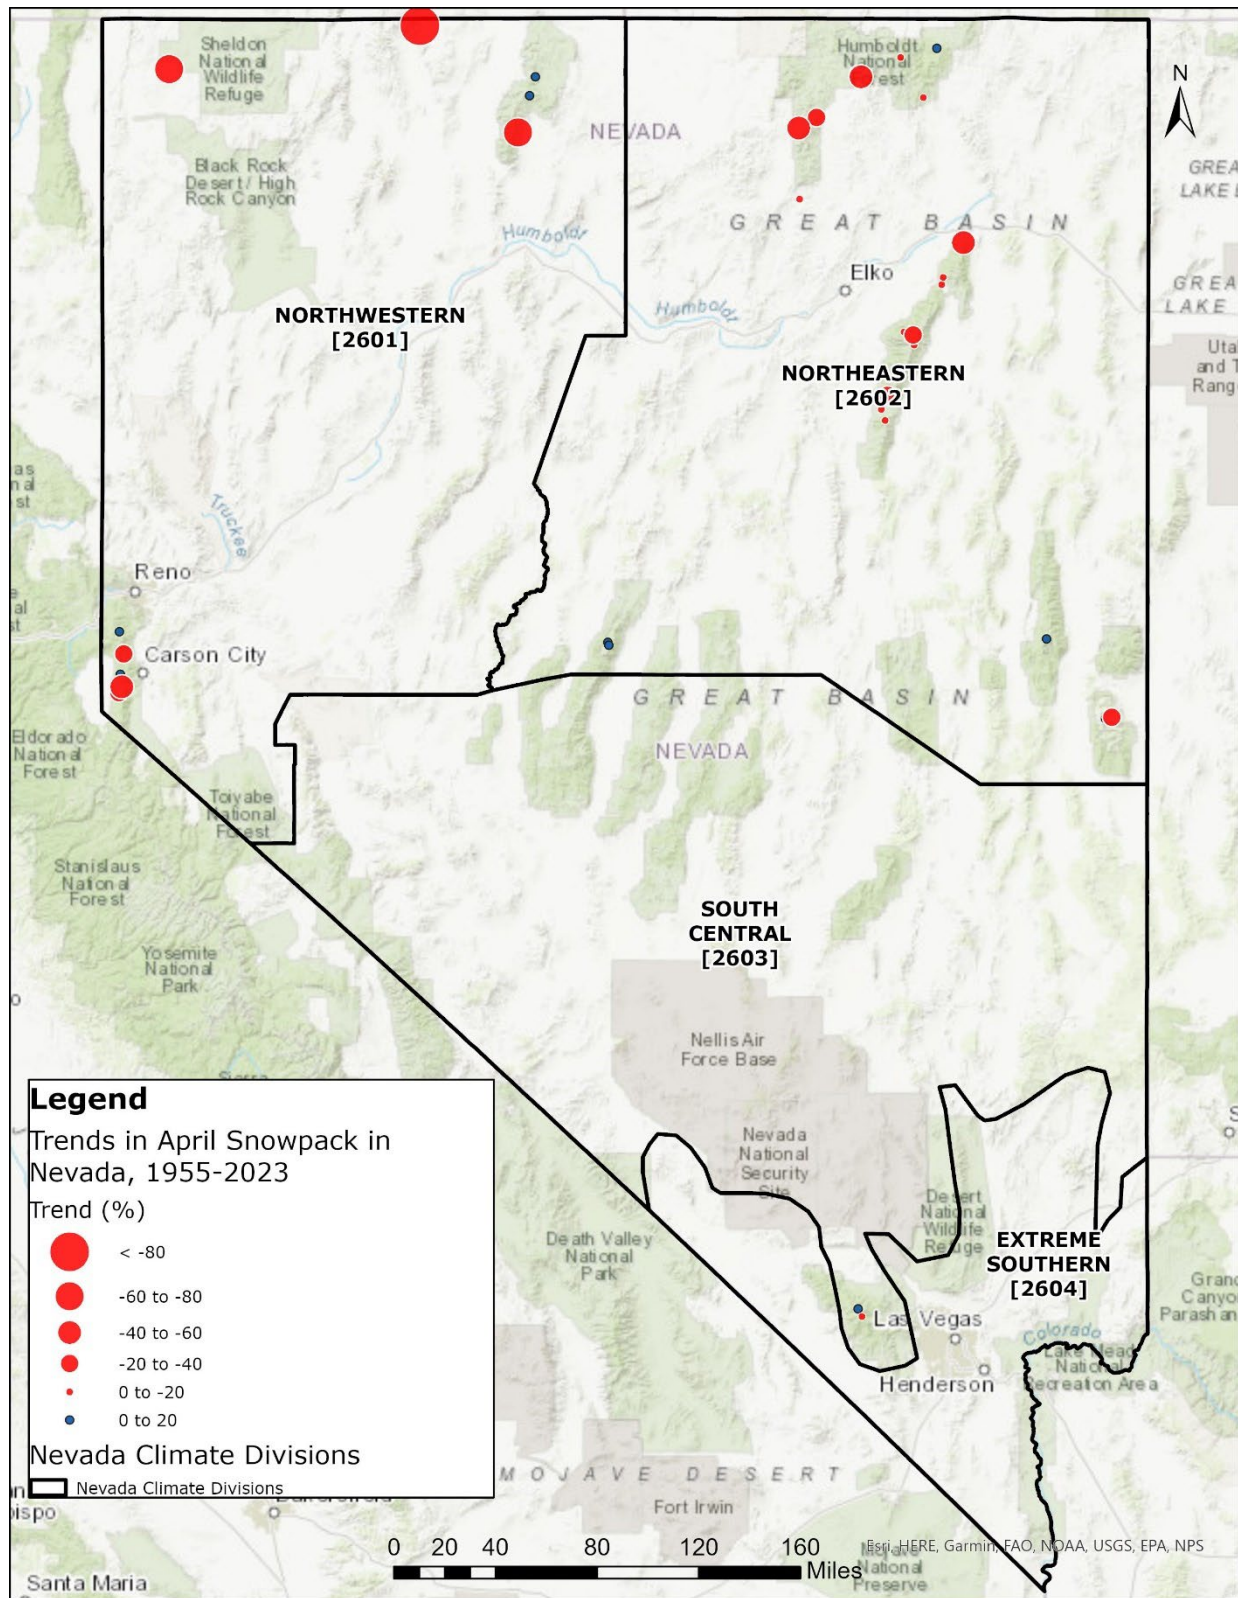

Table 8: Trends in April Snowpack in Nevada, 1955-2023

Site Latitude	Site Longitude	Trend (%)

¹⁴ SWE is a measurement of the amount of liquid water contained within the snowpack.

Figure 8: Trends in April Snowpack in Nevada, 1955-2023

(USEPA 2024f)

Higher spring temperatures will also result in earlier melting of the snowpack, further decreasing water availability and diminishing water quality during the already dry summer months (Runkle et al 2022).

Smaller snowpacks that melt earlier could lead to a longer summer dry season. Desert terminal lakes in Nevada will likely have lower lake levels and increased salinity which will endanger fisheries (McAfee et al 2021).

In addition, the timing of water release from reservoirs could be affected by earlier snowmelt. An earlier snow melt, and more rain rather than snow may stress these systems and lead to more flooding or require dams to release water earlier in the year.

Fish such as trout are dependent on clean, cool water flowing year-round and lower summer flows will mean warmer water temperatures and lower concentrations of dissolved oxygen. This will create challenges for fish and other aquatic life because less suitable habitat will be available. Fish will have to cope with warmer water or swim much farther to find water that is cold enough for them to survive in, especially as air temperatures increase.

How Climate Change Will Impact Snowpack in Nevada

The water cycle describes the movement of water between the Earth's atmosphere, surface, and subsurface. The water cycle is a key factor affecting the physical, chemical, and biological makeup of a water body. Alteration of historical patterns of hydrologic parameters such as snowmelt, runoff, and evaporative demand can inhibit the ability of waters to support aquatic life and provide ecosystem services (e.g., clean and plentiful drinking water, recreational opportunities, etc.).

According to the Fifth National Climate Assessment, there is widespread consensus that increases in air temperature will decrease the proportion of precipitation that falls as snow, decrease snow extents, advance the timing of snowmelt rates and pulses, increase the prevalence of rain-on-snow events, and influence how snow water resources are partitioned to runoff (Jay et al 2023).

The effective capacity of water stored by mountain snowpack has been reduced by recent intense droughts, as well as from earlier snowmelt and runoff as a result of rising temperatures, rain-on-snow events, and enhanced dust on snow (Friedrich et al 2017).

Projected rising temperatures in Nevada will raise the snow line—the average lowest elevation at which snow falls. This will increase the likelihood that precipitation will fall as rain rather than snow, reducing water storage in the snowpack, particularly at those lower mountain elevations that are now on the margins of reliable snowpack accumulation. Projections of annual precipitation for Nevada are uncertain throughout this century, but warmer temperatures are likely to lead to reductions in late winter and spring snowpack,

with potential negative impacts to water supplies. In addition, warmer temperatures will also increase the demand for water (Runkle et al 2022).

With higher air temperatures, more winter storms will bring rain instead of snow, even at high altitudes. In the near term, between 5 and 10 percent more of the precipitation is anticipated to fall as rain rather than snow. Basins around Lake Tahoe and in northwestern Nevada are projected to experience 10 to 15 percent more rain rather than snow. Less snow and earlier snowmelt affect water management in Nevada, as snow serves as a natural reservoir that slowly provides water to downstream agricultural land, communities, and ecosystems (McAfee et al 2021).

With less precipitation falling as snow, and with snowpack melting earlier due to the warming winters, the amount of water in the snowpack on April 1st is projected to decline 30 to 50 percent by the end of century in most basins in the state. These changes are already being observed across the northern parts of Nevada (McAfee et al 2021).

With high confidence, climate models predict that there will be a shift from snow to rain during the winter, and snow will melt earlier in the winter and spring. With no change in precipitation (or even an increase), higher air temperatures alone will lead to a change from snow to rain, which reduces the amount of water that will be stored in winter snowpack for use later in the year (McAfee et al 2021). A reduced snowpack that melts earlier will lead to degraded surface water quality in Nevada.

Indicator: Projected Percent Decrease in March Snow Water Equivalence in HUC12

The **Projected Percent Decrease in March Snow Water Equivalence in the HUC12** indicator measures future projected changes average March SWE relative to historical conditions in a HUC12 subwatershed. This indicator depicts average SWE in the HUC12 during the month of March that is projected for the years 2061 to 2090, expressed as a percentage change from the historical March average during 1971 to 2000.¹⁵ Positive values indicate a projected decrease in average March SWE during 2061-2090 relative to historical 1971-2000 conditions. This indicator reflects the RCP 8.5 greenhouse gas emission scenario (USEPA 2022b, 2023a, and 2024b).¹⁶

This indicator can be used to build awareness of projected decrease in March SWE in one or more HUC12s and to assess the vulnerability of HUC12s to future degradation due to climate change.

The 266 HUC12s in Nevada with a projected decrease in March SWE of 0% were removed from this vulnerability assessment because they likely never had snowpack in March regardless of climate change.¹⁷ 2,056 HUC12 in Nevada have a projected decrease in March SWE between 25.38% and 99.64%. The remaining 242 HUC12s have a projected decrease in March SWE of 100% meaning that spring snowpack will no longer be present in these subwatersheds in the future (USEPA 2023a).

Table 9: Projected Decrease in March SWE Vulnerability Summary

Climate Vulnerability Range	Projected Decrease in March SWE	HUC12 Ranking
Most Vulnerable (Least Resilient)	97.3700001% – 100%	1 – 459
More Vulnerable	93.7200001% – 97.3700000%	460 – 916
Medium Vulnerable	88.9500001% – 93.7200000%	917 – 1,378
Less Vulnerable	79.8800001% – 88.9500000%	1,379 – 1,838
Least Vulnerable (Most Resilient)	25.3800000% – 79.8800001%	1,839 – 2,298

(USEPA 2023a)

¹⁵ During the month of March, the snowpack is typically at or near its maximum depth in the western US (USEPA 2024b).

¹⁶ March SWE during the future and historical periods is calculated from water balance models that simulate the hydrologic response to 30 climate models. The water balance model simulates the combined effects of precipitation and temperature changes independent of land use and vegetation cover. Analysis of climate model results and water balance modeling was completed by the USGS National Climate Change Viewer program (<https://www2.usgs.gov/landresources/lcs/nccv.asp>) (USEPA 2023a and 2024b).

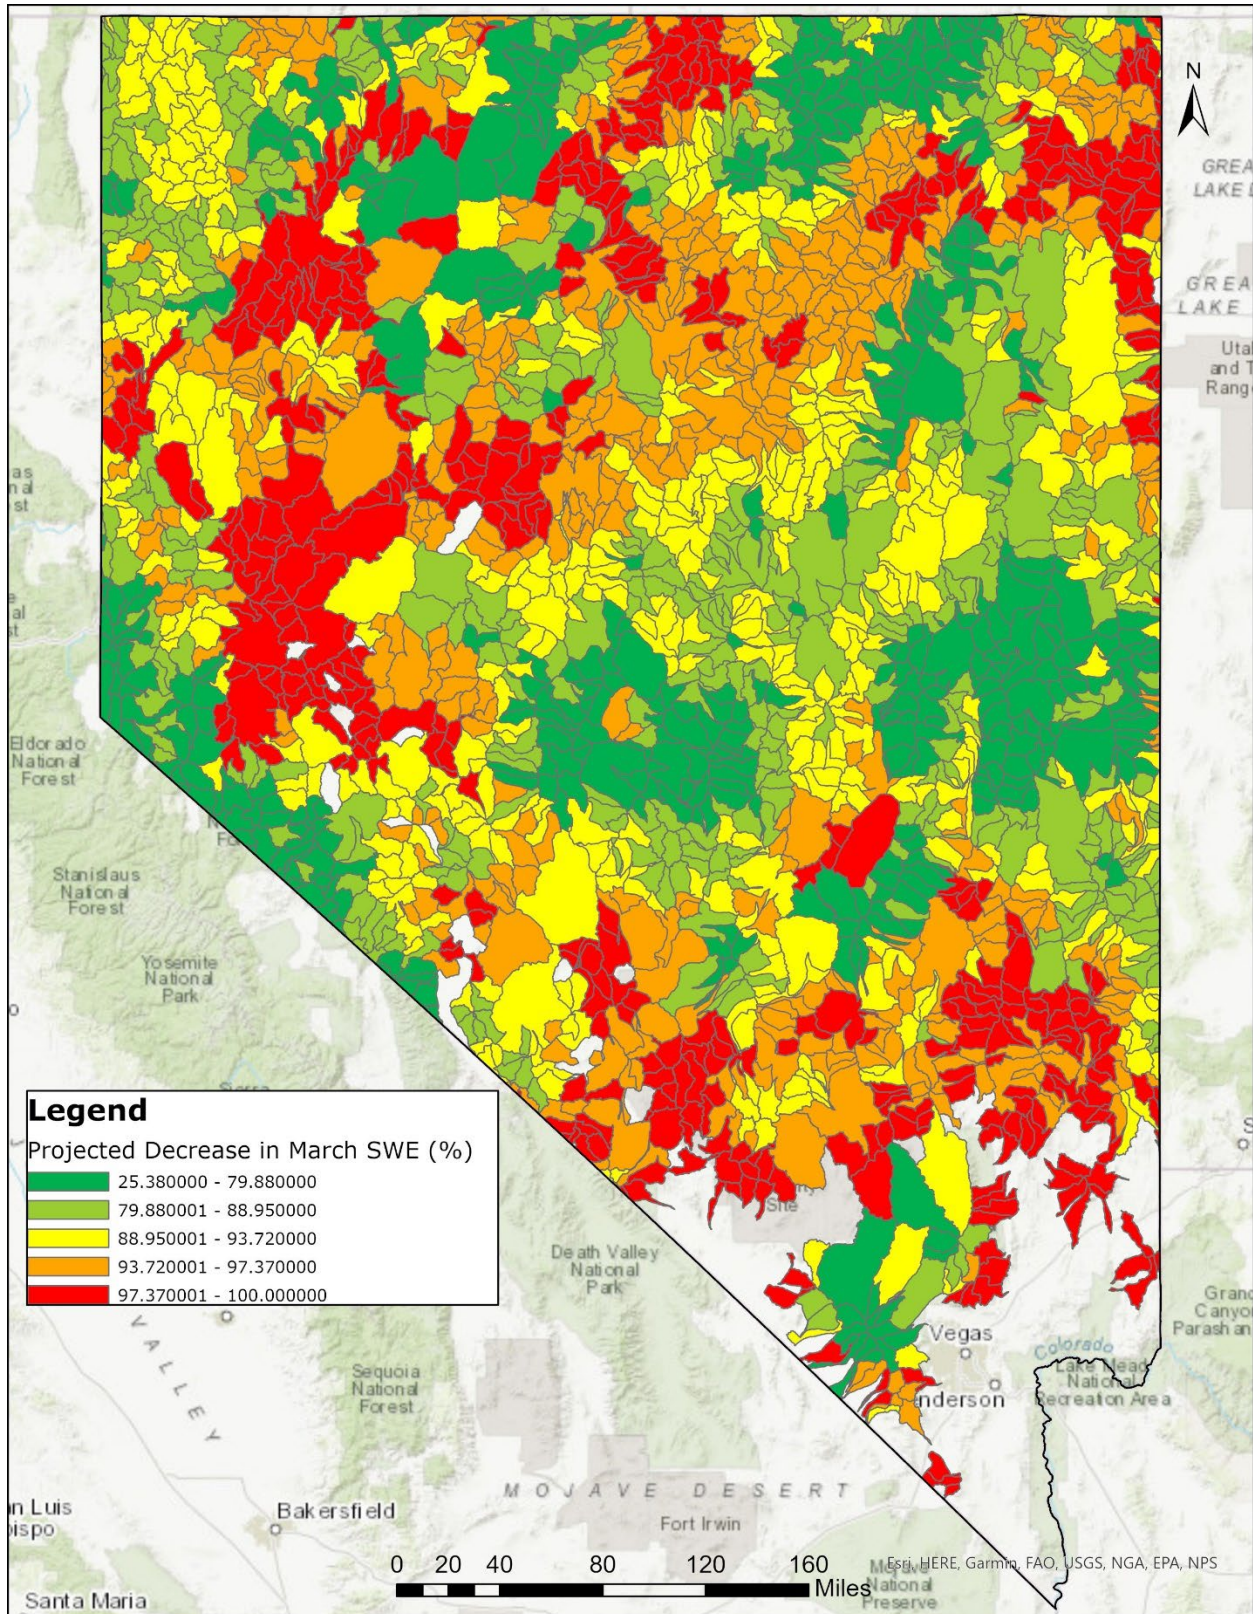

¹⁷ Most of the 226 HUC12s with a projected decrease in March SWE of 0% are in low elevation areas of southern Nevada where snowfall is infrequent.

See ***Appendix E: Projected Percent Decrease in March Snow Water Equivalence Data*** for the full data set.

Indicator Takeaway

A reduced snowpack that melts earlier in the year will lead to degraded surface water quality in Nevada.

Figure 9: Projected Decrease in March Snow Water Equivalence (%)

(USEPA 2023a)

Runoff and Water Quality

Runoff is the amount of water that moves across the landscape into waterbodies. Runoff is generated when rainfall or snowmelt occurs at a faster rate than the land surface can absorb, or when soils become saturated and cannot hold additional water (USEPA 2022b).

The seasonality, frequency, and intensity of runoff all influence whether changing runoff patterns will improve or degrade water quality.

Similar to increased precipitation, increased runoff can improve water quality because higher streamflow is important for dilution of pollutants (USEPA 2024d).

However, increased runoff can intensify erosion and flush additional pollutants from land into water bodies. Such increases in sediment and pollutant delivery can degrade water supplies, inhibit recreational uses, and harm aquatic life. Extreme floods can further increase pollutant levels due to inadequate or failing drainage, flood control, or wastewater infrastructure (USEPA 2022c). Increased runoff can correspond to greater flushing of pollutants from the land into waters, where they can harm environmental and human health. Increased runoff may also result in severe flooding that can erode channels and shorelines, disturb aquatic habitat, and disrupt drinking water and wastewater systems (USEPA 2022b).

Reduced runoff and increased aridity can also contribute to water supply shortages and stress aquatic life by reducing and isolating available habitat, drawing down dissolved oxygen levels, and increasing water temperatures. Stagnant pools of water can foster harmful algal blooms, and low water levels can reduce the capacity for rivers and lakes to dilute discharges from pollutant sources (USEPA 2022b). Changes in precipitation and runoff timing, coupled with higher temperatures due to climate change, may lead to diminished reservoir water quality (USEPA 2024c).

The relationship between runoff and water quality is difficult to establish because runoff influences water quality through many hydrological and biochemical mechanisms.

How Climate Change Will Impact Annual Runoff in Nevada

Average annual surface runoff is projected to decrease in 42 percent of HUC12s in Nevada and increase in 58 percent of HUC12s in Nevada (USEPA 2023a).

Climate change will also impact peak annual runoff rates, the maximum daily runoff rate occurring during the average year. Projected near-term and long-term changes in peak annual runoff rates are projected to increase more than 25% to 50% above historical peak rates across much of the state, especially in and around many mountain ranges (McAfee et al 2021).

It is important to understand how climate change will impact runoff patterns in Nevada so projections of future changes in runoff relative to historical conditions are included in this report. However, conclusions about the climate vulnerability of watersheds will not be drawn based on runoff indicators because of the variability of how changes in runoff will impact water quality in Nevada.

Indicator: Projected Percent Change in Annual Runoff in HUC12

The **Projected Percent Change in Annual Runoff in the HUC12** indicator measures projected future changes in annual runoff in a HUC12 subwatershed relative to historical conditions. Positive values indicate a projected increase in average annual surface runoff from 2061 to 2090 relative to historical conditions from 1971 to 2000; negative values indicate a projected decrease. This indicator reflects the RCP 8.5 greenhouse gas emission scenario (USEPA 2022b and 2024b).¹⁸

This indicator can be used to build awareness of projected hydrologic changes in one or more HUC12s and to assess the vulnerability of HUC12s to future degradation due to climate change.

Average annual surface runoff is projected to decrease in 1,072 of the HUC12s in Nevada (42%). Average annual surface runoff is projected to increase in 1,492 of the HUC12s in Nevada (58%). Average annual surface runoff is projected to not change in HUC12 160402030204 – Cottonwood Creek (USEPA 2023a).

Table 10: Projected Change in Annual Runoff Summary¹⁹

Change Category	Projected Change in Annual Runoff	HUC12 Ranking
Largest Decrease	-20% to -30%	1 – 4
Medium Decrease	-10% to -20%	5 – 111
Smallest Decrease	0% to -10%	112 – 1,072
Smallest Increase	0% to 10%	1,073 – 2,035
Medium-Small Increase	10% to 20%	2,037 – 2,422
Medium-Large Increase	20% to 30%	2,433 – 2,560
Largest Increase	30% to 40%	2,561 – 2,564

(USEPA 2023a)

¹⁸ Annual surface runoff during the future and historical periods is calculated from water balance models that simulate the hydrologic response to 30 climate models. The water balance model simulates the combined effects of precipitation and temperature changes independent of land use and vegetation cover. Analysis of climate model results and water balance modeling was completed by the USGS National Climate Change Viewer program (<https://www2.usgs.gov/landresources/lcs/nccv.asp>) (USEPA 2024b).

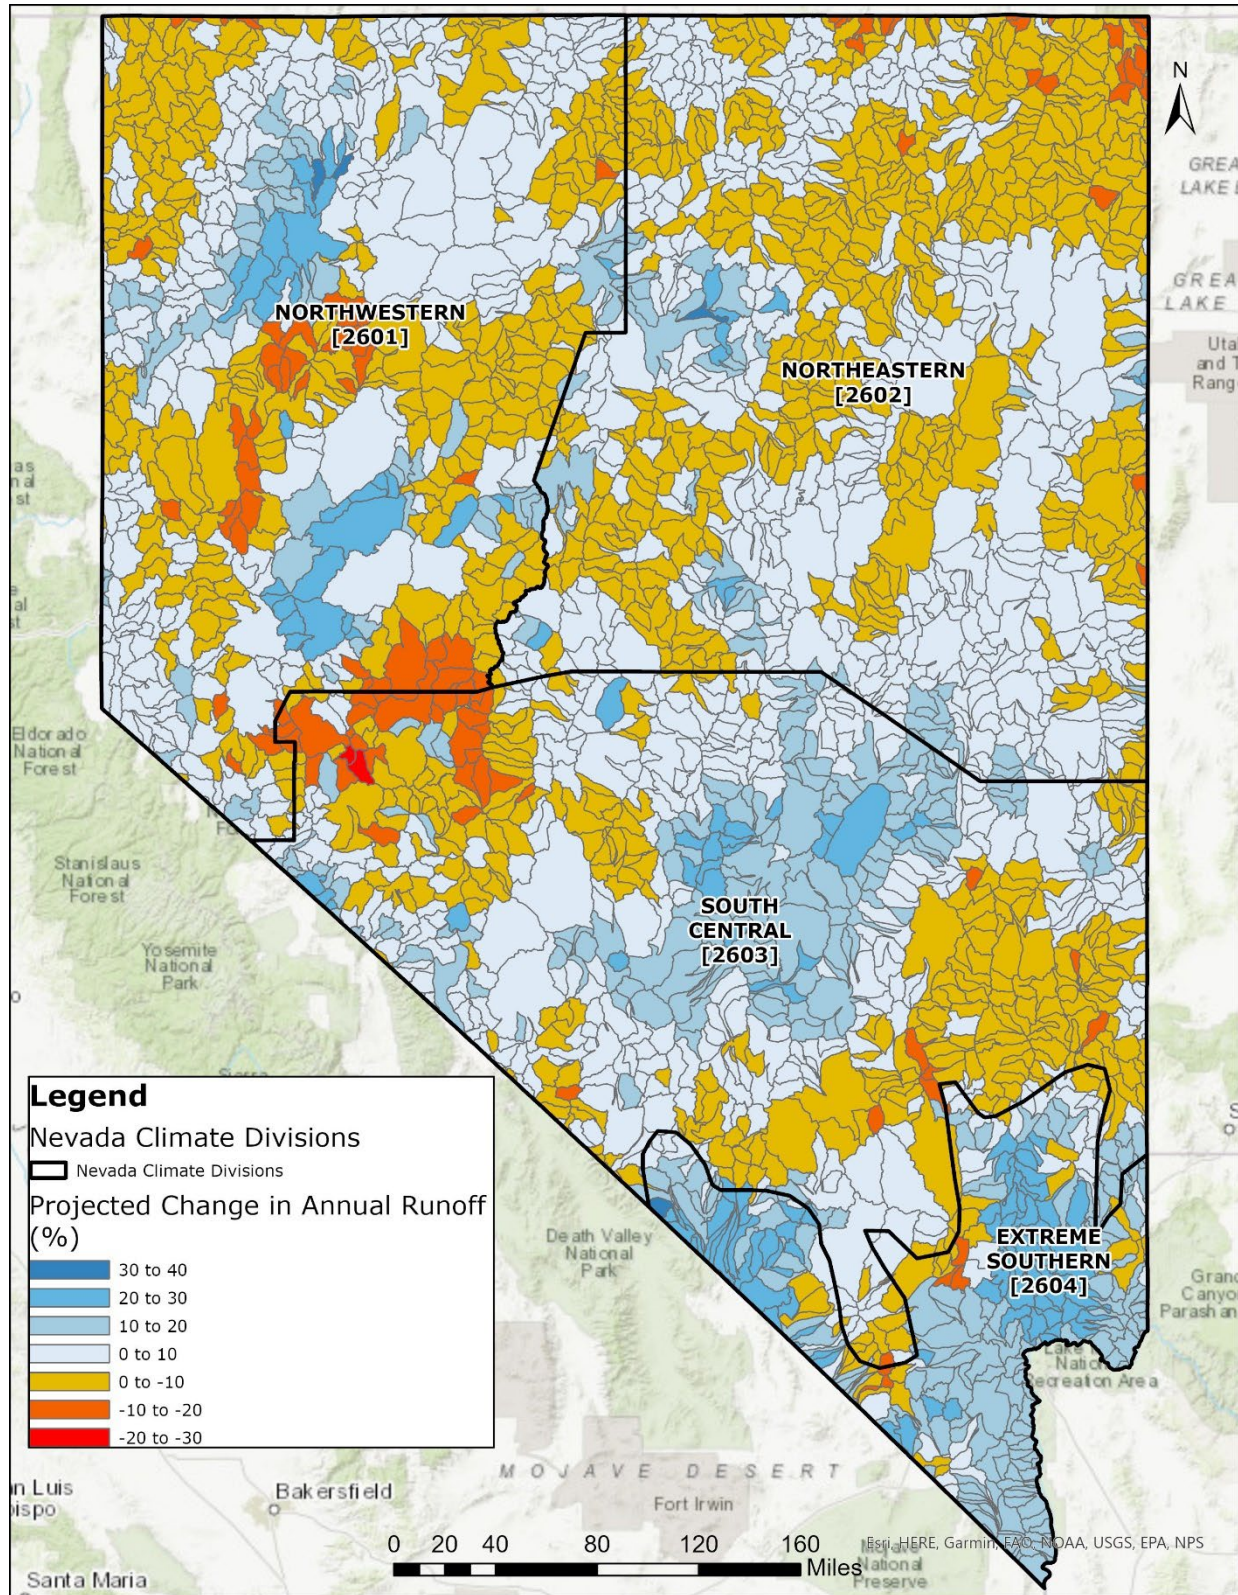

¹⁹ The Projected Change in Annual Runoff summary (**Table 10** and **Figure 10**) were created using the Defined Interval data classification method (ESRI 2024).

See ***Appendix F: Projected Percent Change in Annual Runoff Data*** for the full data set.

Indicator Takeaway

Conclusions about the climate vulnerability of watersheds will not be drawn based on the annual runoff indicator because of the variability of how changes in annual runoff will impact water quality in Nevada.

Figure 10: Projected Change in Annual Runoff (%)

Evaporative Deficit and Water Quality

Evaporative demand—the atmospheric thirst driven by temperature, wind, humidity and solar radiation—plays an important role in droughts and can be particularly impactful in arid places such as Nevada (McAfee et al 2021).²⁰ Evaporative deficit is a measure of aridity or atmospheric water shortage, quantified as the difference between potential evapotranspiration and actual evapotranspiration. As average temperatures have risen because of climate change, the rate of water evaporation from the Earth's surface (including soil, lakes, and reservoirs) and transpiration (the process of losing water) from plants has risen as well. This has sped up the Earth's water cycle. An increase in evapotranspiration (the transfer of water from land to the atmosphere) makes more water available in the air for precipitation, but it also leaves less moisture in the soil (USEPA 2024a).

Drought is a critical climate threat for Nevada (Runkle et al 2022). Droughts are driven by many factors, including unsupportable societal demands for water. From a climate perspective, below-normal precipitation is a primary driver of drought, but there is growing acknowledgement that higher temperatures can cause drought to develop or become more intense than would be expected from precipitation deficits alone; higher temperatures drive increased atmospheric demand for moisture—a phenomenon known as hot drought. Temperature's contribution to drought makes it clear that warming associated with climate change could increase the frequency, severity, and/or duration of drought and drive aridification, a long-term shift toward a drier climate, which is a concern in already dry parts of the West (Jay et al 2023).

Higher air temperatures lead to increased evaporative demand, which reduces water availability. Higher air temperatures and less water in water bodies can lead to poor water quality. Droughts also increase demand for agricultural and household use, further stressing water resources (McAfee et al 2021). Excess salinity can occur in areas where evaporation is high and made worse by repeated use of water for irrigation or water withdrawals. Salts can make water unsafe for beneficial uses including municipal or domestic supply, irrigation, and watering of livestock and can be toxic to freshwater aquatic life.

Increased aridity and reduced runoff can contribute to water supply shortages and stress aquatic life by reducing and isolating available habitat, drawing down dissolved oxygen levels, and increasing water temperatures. Stagnant pools of water can foster harmful algal blooms, and low water levels can reduce the capacity for rivers and lakes to dilute discharges from pollutant sources (USEPA 2022b).

Climate change may cause summer droughts to increase in intensity and duration worldwide. During a drought, the amount of water flowing into lakes and reservoirs

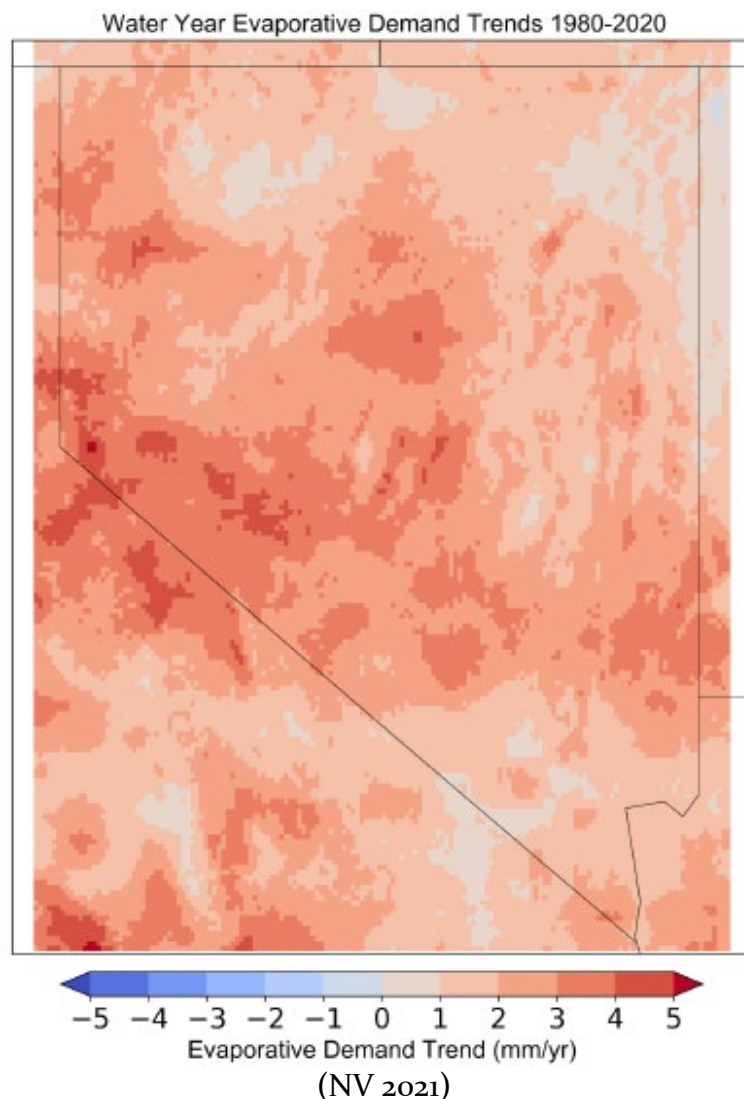

²⁰ Evaporative demand is also known as potential evapotranspiration (Jay et al 2023).

decreases. Combined with warmer temperatures that cause more evaporation, water levels of freshwater bodies decrease. This causes the salinity in the water body to increase (USEPA 2013).

How Climate Change Will Impact Evaporative Deficit

Over the past 40 years, evaporative demand has strongly increased in Nevada, with the fastest increases in the west-central part of the state. Evaporative demand has increased almost everywhere in the State, amounting to between 20 and 200 extra millimeters of demand over the 40-year period from 1980 to 2020 (NV 2021). Recent precipitation shortages, combined with increasing evaporation, have already led to hydrologic (water supply) droughts being more common since the start of the 21st century (McAfee et al 2021). Climate projections indicate that evaporative demand will continue to increase in Nevada (NV 2021).

Figure 11: Observed trends total evaporative demand for the period 1980–2020

Throughout Nevada, drought conditions have increased from 1900 to 2023. One measure of drought that accounts for both precipitation and evaporative demand is the Standardized Precipitation Evapotranspiration Index (SPEI) which has been found to be a good indicator of low streamflows and lake/reservoir levels in Nevada (McEvoy et al 2012). The Extreme Southern (2604) climate division experienced the largest average change in drought (5-year SPEI) of -2.505822 (USEPA 2024a). Negative values in **Table 11** represent decreased moisture/drier conditions.

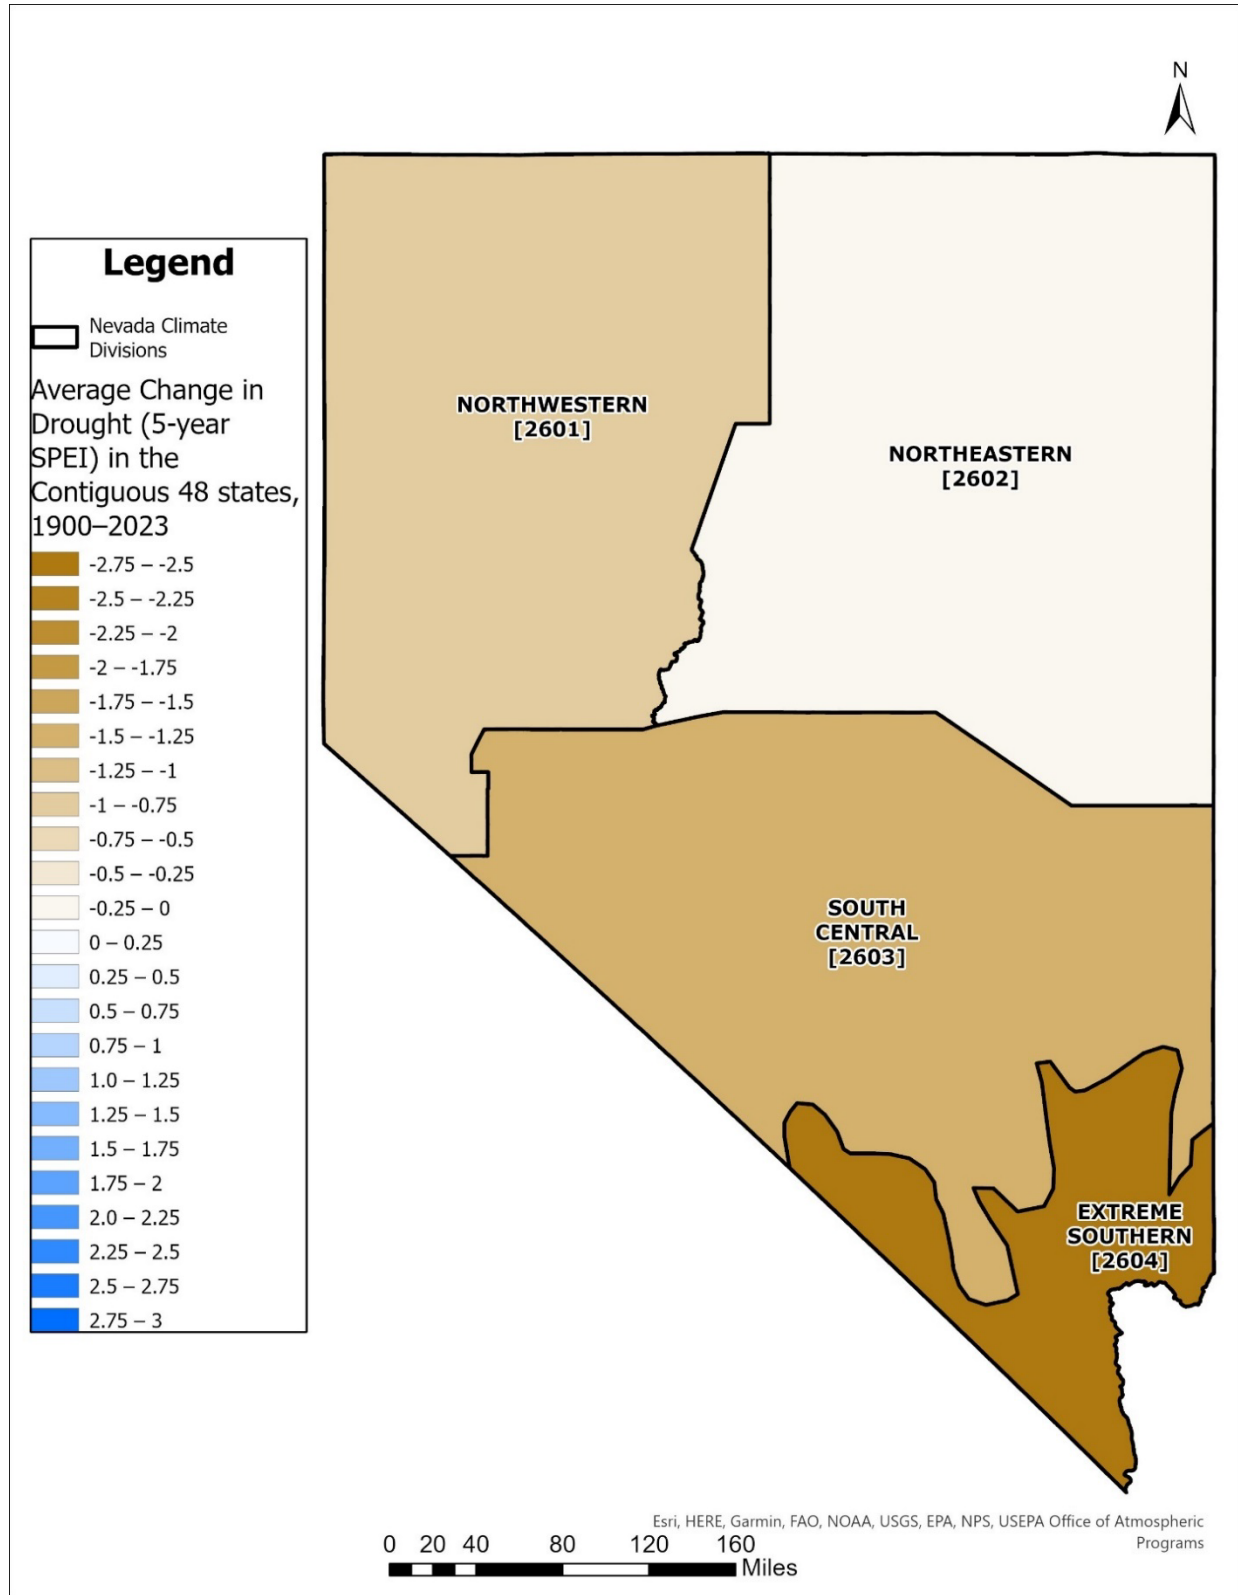

Table 11: Average Change in Drought (5-year SPEI) in Nevada, 1900-2023

Nevada Climate Division	Average Change in Drought (5-year SPEI)
1 – Northwestern (2601)	-0.917
2 – Northeastern (2602)	-0.025
3 – South Central (2603)	-1.323
4 – Extreme Southern (2604)	-2.506

(USEPA 2024a)

Figure 12 shows the total change in drought conditions across Nevada, based on the long-term average rate of change in the five-year SPEI from 1900 to 2023. SPEI measures the combination of water supply (precipitation) and atmospheric water demand (evapotranspiration, which is based on temperature) to determine whether a certain area is experiencing extreme drought, extreme moisture, or conditions in between. Brown areas represent decreased moisture/drier conditions (USEPA 2024a).

Figure 12: Average Change in Drought (5-year SPEI) in Nevada, 1900-2023

(USEPA 2024a)

The effects of climate change and rising temperatures threaten to reduce available surface water through enhanced evaporation especially in arid regions such as Nevada (Friedrich et al 2017). Higher temperatures will also increase the evaporation rate, which will reduce streamflow and soil moisture. Thus, the intensity of future droughts is likely to increase, as will the risk of wildfires in some ecosystems (Runkle et al 2022).

With high confidence, climate projections indicate that evaporative demand will continue to increase through the end of the 21st century and hydrologic (water supply) droughts will occur more frequently and be more severe (McAfee et al 2021).

Indicator: Projected Percent Change in Annual Evaporative Deficit in HUC12

Evaporative deficit is a measure of aridity or atmospheric water shortage, quantified as the difference between potential evapotranspiration and actual evapotranspiration. The **Projected Percent Change in Annual Evaporative Deficit in the HUC12** indicator measures projected future changes in evaporative deficit in a HUC12 subwatershed relative to historical conditions. Positive values indicate a projected increase in average annual evaporative deficit during 2061-2090 (i.e., drier conditions) relative to historical 1971-2000 conditions. This indicator reflects the RCP 8.5 greenhouse gas emission scenario (USEPA 2022band 2024b).²¹

This indicator can be used to build awareness of projected hydrologic changes in one or more HUC12s and to assess the vulnerability of HUC12s to future degradation due to climate change.

Annual evaporative deficit is projected to increase in all 2,564 HUC12s in Nevada (USEPA 2023a).

Table 12: Projected Change in Annual Evaporative Deficit Vulnerability Summary

Climate Vulnerability Range	Projected Change in Annual Evaporative Deficit	HUC12 Ranking
Most Vulnerable (Least Resilient)	43% – 127%	1 – 472
More Vulnerable	38% – 42%	473 – 949
Medium Vulnerable	32% – 37%	950 – 1,487
Less Vulnerable	26% – 31%	1,488 – 2,026
Least Vulnerable (Most Resilient)	11% – 25%	2,025 – 2,564

(USEPA 2023a)

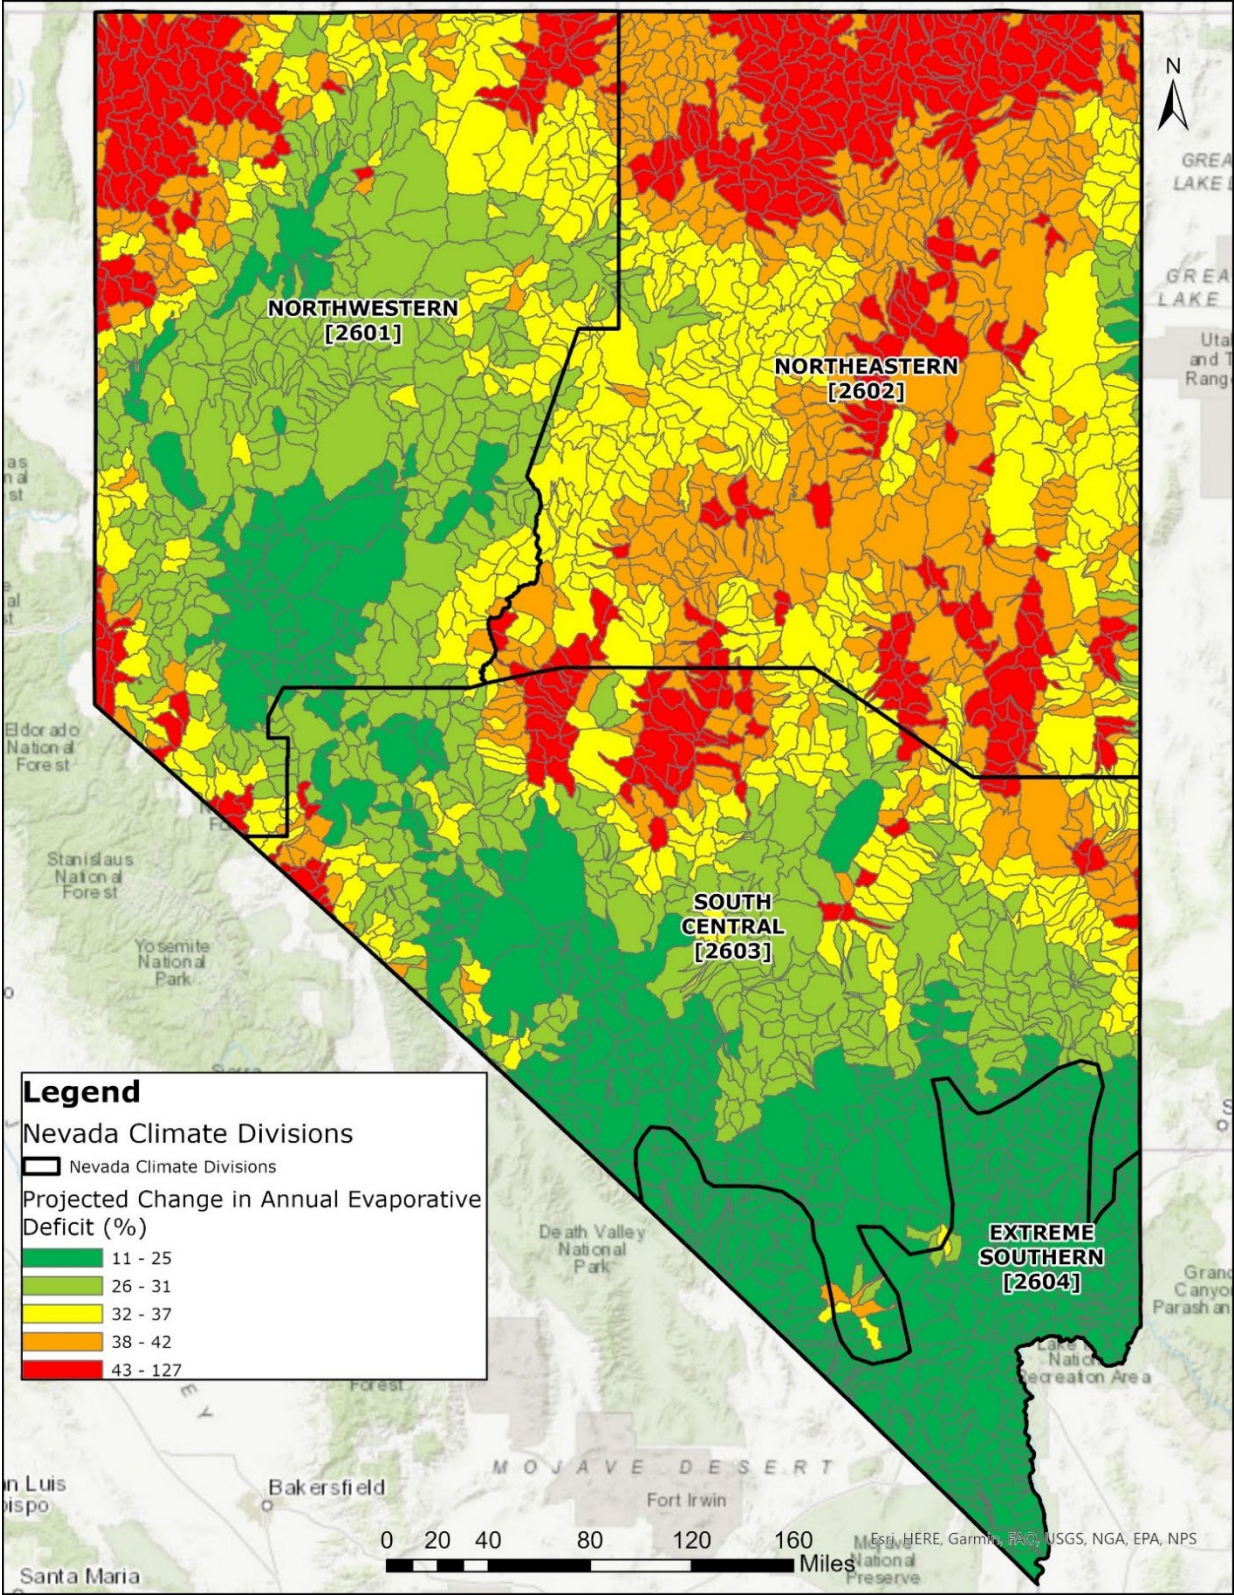

See **Appendix G: Projected Percent Change in Annual Evaporative Deficit Data** for the full data set.

Indicator Takeaway

There is a strong, direct relationship between increased evaporative demand and degraded water quality. Based on this indicator, water quality across Nevada will be degraded.

²¹ Annual evaporative deficit during the future and historical periods is calculated from water balance models that simulate the hydrologic response to 30 climate models. The water balance model simulates the combined effects of precipitation and temperature changes independent of land use and vegetation cover. Analysis of climate model results and water balance modeling was completed by the USGS National Climate Change Viewer program (<https://www2.usgs.gov/landresources/lcs/nccv.asp>).

Figure 13: Projected Change in Annual Evaporative Deficit (%)

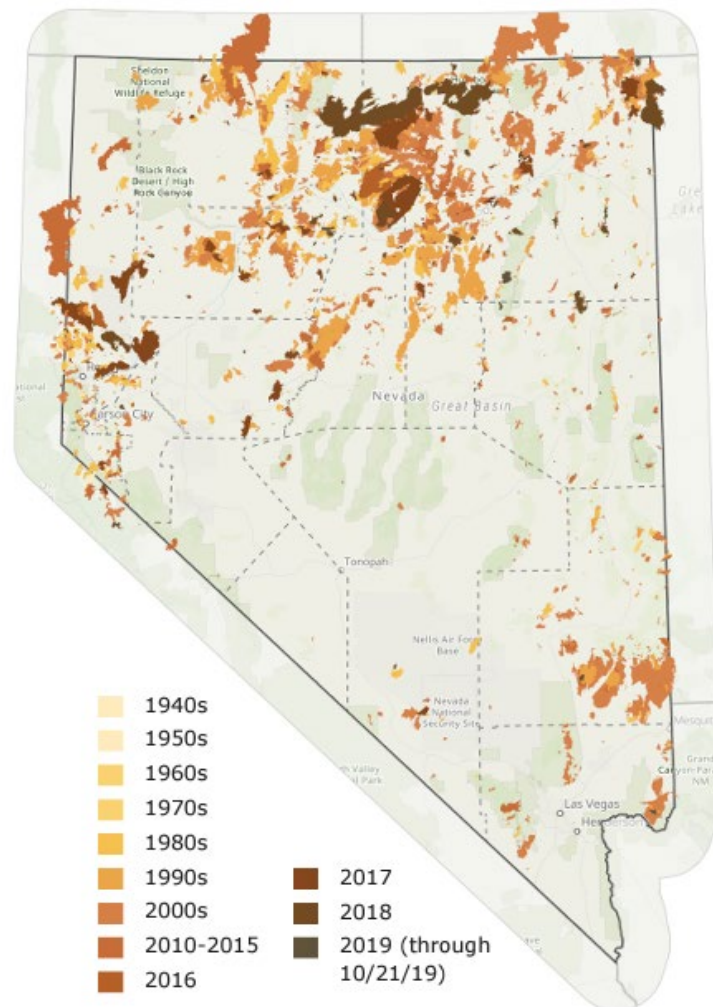

Wildfire and Water Quality

While wildfires occur naturally and play a long-term role in the health of ecosystems such as forests, shrubland, and grassland, changing wildfire patterns threaten to upset the status quo. Many studies have found that climate change has already led to an increase in wildfire season length, wildfire frequency, and burned area. This is a result of factors such as higher temperatures, longer summer dry seasons and increased drought conditions, and warmer spring weather with less snowpack to supply water throughout the summer (USEPA 2024a). Wildfires substantially alter aquatic ecosystems by inducing moderate to catastrophic physical and chemical changes (Elliott et al 2024).

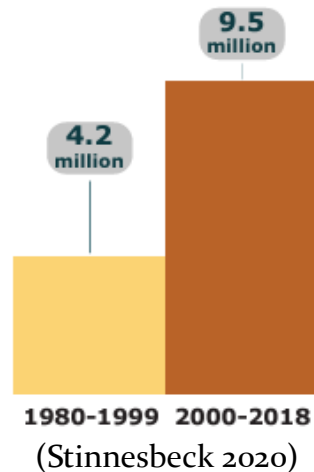

When evaporative demand is higher than normal as it is in Nevada, soils dry out faster and vegetation becomes drier, leading to increased fire risk and degraded ecosystems. Wildfire size and severity have already increased in Nevada (McAfee et al 2021).

Figure 14: Nevada Wildland Fire History, 1941-2019

(Stinnesbeck 2020)

Figure 15: Number of Acres Burned by Wildfire in Nevada

As a result of vegetation loss, wildfires can cause changes in hydrologic processes such as overland flow, interception, evapotranspiration, and as a result can increase runoff, erosion, and sediment delivery (USEPA 2021b). Fire frequency, severity, and areal extent alter hydrologic processes within the watershed through vegetation removal, alteration of soil properties, and related shifts in overland flow, infiltration, recharge, and baseflow discharge to streams. In addition to hydrologic processes, fire characteristics alter biogeochemical processes (Elliott et al 2024).

Vegetative cover loss from wildfires can increase runoff potential and alter historic flow regimes, increase sediment and nutrient loading, and increase water temperatures (USEPA 2024b). The risk of debris flows and erosion can increase after wildfire, leading to reduced water quality and changes in water supply (McAfee et al 2021). Increased in-stream nitrogen, phosphorus, metal, and carbon concentrations were the most reported water-quality stressors downstream from burned areas (Elliott et al 2024). Wildfires can also deposit airborne fire debris which can encapsulate aquatic habitat as it settles, or cause fish kills via oxygen depletion through the decomposition process. Additionally, wildfire management often involves the use of flame-retardant chemicals which can be harmful to aquatic organisms (USEPA 2024b).

During active burning, ash and contaminants associated with ash settle on streams, lakes and water reservoirs. Vegetation that holds soil in place and retains water is burned away. In the aftermath of a large wildfire, rainstorms flush vast quantities of ash, sediment, nutrients and contaminants into streams, rivers, and downstream reservoirs. The absence of vegetation in the watershed can create conditions conducive to erosion and even flooding, and naturally occurring and anthropogenic substances can impact drinking water quality, discolor recreational waters, and may potentially contribute to harmful algal blooms (USEPA 2019).

How Climate Change Will Impact Wildfire Activity in Nevada

With high confidence, climate models predict that the frequency and severity of wildfires are projected to increase in Nevada (McAfee et al 2021 and Runkle et al 2022).

As mentioned above, winter precipitation is projected to increase throughout Nevada, which can increase wildfire risk through more vegetation and fuels growth (particularly grasses and small shrubs). In addition, increased evaporative deficit in the spring and summer will amplify wildfire risk by desiccating vegetation faster.

Indicator: PHWA Wildfire Vulnerability Sub-Index, State

The 2021 Preliminary Healthy Watersheds Assessment (PHWA) conducted by the USEPA Healthy Watersheds Program characterized watershed health and vulnerability at the HUC12 scale across each state and ecoregion in the contiguous United States. The **PHWA Wildfire Vulnerability Sub-Index, State** indicator depicts the vulnerability of aquatic ecosystems in a HUC12 to the effects of intense wildfires based on a predictive model of wildfire risk in the HUC12 (USEPA 2024b). Values for this indicator range from 0 to 1, where higher values denote more vulnerable (less resilient) watersheds (USEPA 2021b).²²

Table 13: PHWA Wildfire Vulnerability Sub-Index, State Vulnerability Summary

Climate Vulnerability Range	PHWA Wildfire Vulnerability Sub-Index, State	HUC12 Ranking
Most Vulnerable (Least Resilient)	0.722300 – 1.0	1 – 514
More Vulnerable	0.455906 – 0.722299	515 – 1,026
Medium Vulnerable	0.259715 – 0.455905	1,026 – 1,536
Less Vulnerable	0.106613 – 0.259714	1,537 – 2,051
Least Vulnerable (Most Resilient)	0 – 0.106612	2,052 – 2,564

(USEPA 2023a)

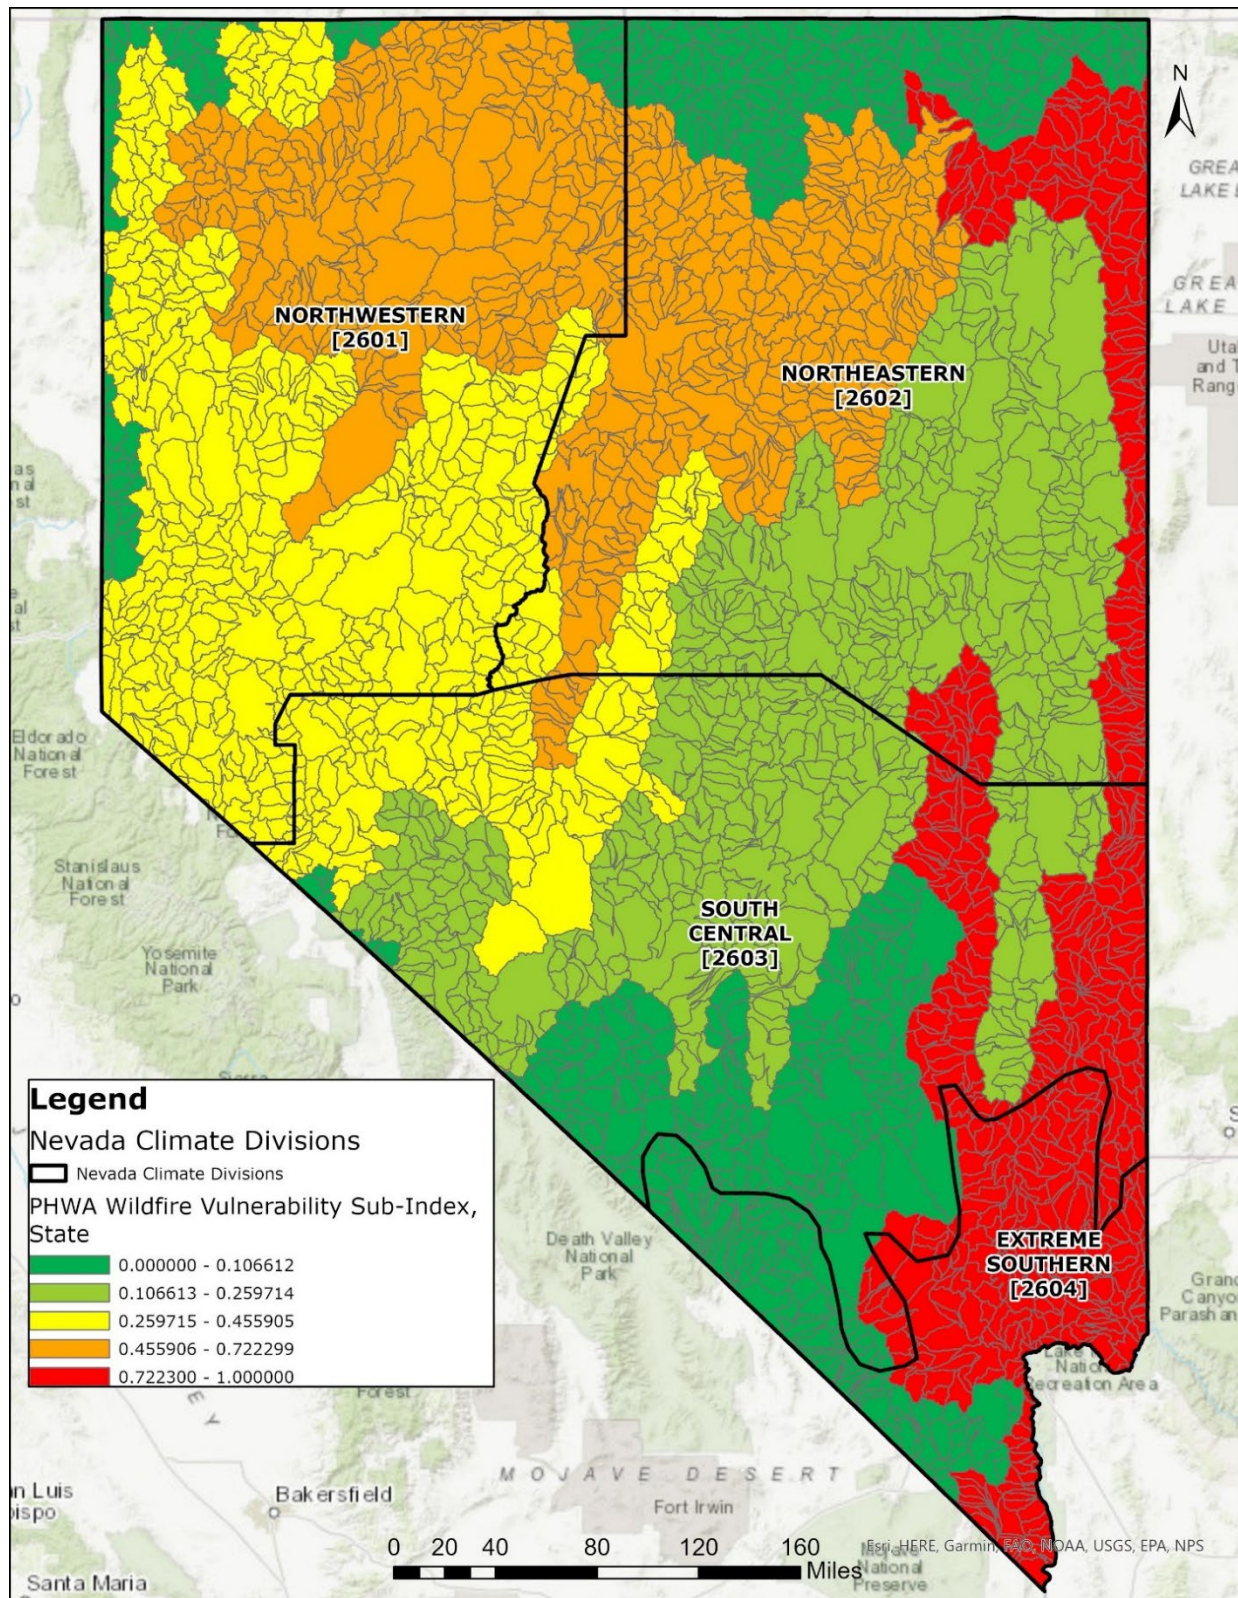

See **Appendix H: PHWA Wildfire Vulnerability Sub-Index, State Data** for the full data set.

Indicator Takeaway

Climate change will increase the frequency, severity, and areal extent of wildfires across Nevada which will result in degraded surface water quality.

²² Source data were statewide Wildfire Vulnerability Sub-Index scores for HUC12s developed as part of the 2021 EPA Preliminary Healthy Watersheds Assessment (August 8, 2021 version). NOTE: PHWA scores/percentiles are not suitable for comparing HUC12s that occur in different states to one another. Scoring of a given HUC12 reflects its condition relative to all other HUC12s within the same state only (USEPA 2024b).
